July 6–7, 2023

### Abstract

India was an outlier on fiscal outcomes pre-pandemic, before drifting further in the high debt direction during COVID. Its debt-to-GDP ratio is not likely to fall anytime soon. Current high levels of debt limit the resources available for other priorities such as health, education and climate change abatement. At the same time, there is no immediate crisis of debt sustainability: institutional factors limit rollover risk, and interest rates have not risen with additional debt issuance. But financial stability and sustainability risks may arise in the future, and lack of resources to meet pressing needs is a drag on growth. Consolidation would require lower primary deficits achieved through greater tax revenue generation and privatization, all while protecting and prospectively increasing capital spending. Contingent liabilities have posed risks to the public finances of the States and should be minimized by fiscal-management reforms. As their debt manager, the RBI should ensure that States face the market interest rates warranted by their current and projected debt levels. Fiscal Commissions should provide stronger incentives for prudence.

## 1. Introduction

India's public finances paint a mixed picture. The country was an outlier in fiscal outcomes before the pandemic. Its fiscal deficits and public debts were among the highest in the developing world; its interest payment/GDP ratio and primary deficits were large. The pandemic reinforced these trends. At their peak in 2020-21, the debt and deficit stood at 89 and 13 per cent of GDP respectively. (Contingent liabilities – the present value of the prospective stock – are estimated at an additional 5 per cent of GDP). A large part of the additional public debt accumulated during COVID was incurred by the Central Government, while a majority of the debt accumulated in pre-COVID years was owed by the States. With the recovery of nominal GDP, the country's debt and deficit ratios have fallen from these multi-decade highs. But at 84 and 9 per cent, they are still high relative to other emerging market and middle-income countries, where they average 60 and 5 percent.<sup>1</sup>

In this paper we assess the sustainability of the public finances, with a focus on the next five years.

A first criterion for sustainability is whether the debt ratio will remain stable. We find, under reasonable assumptions, that the debt ratio will remain broadly stable. This stability rests on the assumption of a largely unchanged primary budget deficit and a favorable growth-rate-interest-rate differential, the latter reflecting India's positive growth prospects and also institutional factors limiting upward pressure on interest rates. The institutional factors in question include a captive market for public debt among state banks, private banks, insurance companies and provident funds. Together with household savings, these have enabled the government to fund its deficits without undue pressure on borrowing costs.

A second for sustainability is whether there is significant rollover risk. We find that these same factors, together with the currency composition and maturity of the debt, also limit rollover risk. In this respect our conclusions differ from those of Blanchard, Felman and Subramanian (2021).

Counterbalancing these happy conclusions is the unhappy fact that India is unlikely to significantly reduce its debt ratio absent extensive and politically-fraught reforms. Smaller primary budget deficits will be difficult to achieve given pressure for social and infrastructure spending, including on climate-change abatement and adaptation and the green transition, and the difficulty of boosting tax revenues. Faster growth rates or lower interest rates are pleasant to imagine but difficult to achieve.

What are the costs of living with high public debt? First, interest payments will continue to absorb a significant share of the government's resources, limiting their availability for other economic and social priorities. Second, available fiscal resources leave no room for meeting emerging priorities, including health, education, and climate change adaptation. Third, debt dynamics leave little scope for responding to negative shocks, such as declining rates of domestic or global growth. Fourth, having banks hold large amounts of government debt creates financial stability risks; this is the "diabolic loop" seen a decade ago in Europe and in the case of the Silicon Valley Bank. Fifth, and

---

<sup>1</sup> These numbers and the categorization of countries, 95 in number, as "emerging-market and middle income" are from the IMF's *Fiscal Monitor*, April 2023. The fiscal year runs from April to March. For example, fiscal year 2023-24 refers to April 1, 2023-March 31, 2024.

relatedly, with further financial liberalization and reform, the government when marketing its debt may be forced to rely less on captive domestic investors and more on foreign institutional investors. Though rollover risk may be limited now, it may rise in the future with this change in investor composition.

Section 2 summarizes trends in India's public finances, while Section 3 considers salient features of debt composition. Section 4 presents a debt sustainability analysis, after which Section 5 analyzes past episodes of debt consolidation. In Section 6 we assess the implications and risks of the current levels of debt. Section 7 summarizes the implications.

## 2. Debt and Deficits in India

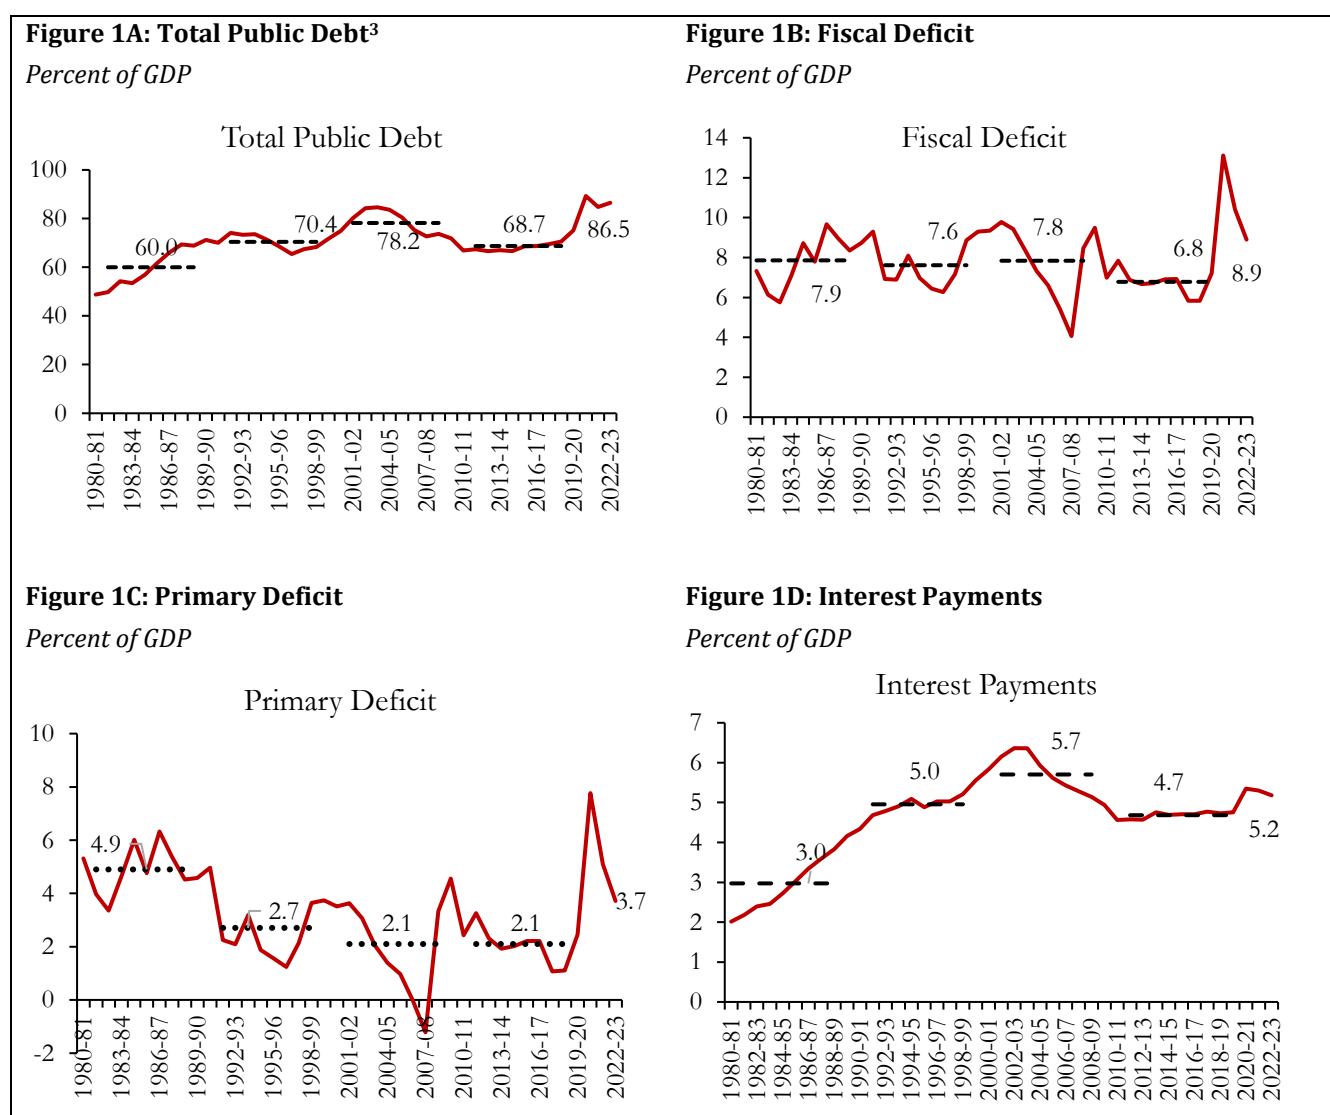

Public debt has not only been high in India, but it has increased markedly over the past four decades (Figure 1). Having averaged 60 percent of GDP in the 1980s, it rose to 70 percent in the 1990s and 80 percent in the 2000s. From these highs, it declined to 69 percent of GDP the following decade, before increasing to nearly 90 percent of GDP in 2020-21 in the wake of COVID and hovering at 85-87 percent for the last two years.

The budget deficit has fluctuated around 7-8 percent of GDP, as shown in Figure 1. It rose to an unprecedented 13.1 percent of GDP in 2020-21. This increase was due mainly to higher expenditure, and to a lesser extent due to slower revenue growth and contraction of nominal GDP. This unprecedented deficit resulted in a commensurately large increase in public debt to nearly 90 percent of GDP, surpassing the previous peak of about 83 percent in the early 2000s.

Interest payments have averaged 5 percent of GDP for three decades. They rose from 11.5 percent of total revenue in 1980-81 to fully a quarter of total revenue in 2022-23. Government spends more on interest than on education and health combined. Interest payments exceed total capital expenditure. The General Government's primary deficit (deficit net of the aforementioned interest payments) averaged a bit over 2 percent of GDP in the two decades preceding COVID. The General Government has in fact run a primary surplus only once in the past 40 years, in 2007-08. Since then, there have been two sharp increases in the primary deficit, to 4.6 percent of GDP in 2009-10 and 7.8 percent of GDP in 2020-21.<sup>2</sup>

---

<sup>2</sup> Subsequently, the primary deficit decline to 3.7 percent in 2022-23.

**Figure 1: General Government (Federal and States) Debt and Fiscal Indicators**

Source: CEIC (Compiled from Reserve Bank of India). Dashed horizontal lines are decadal averages from 1980-81 to 1989-90, 1990-91 to 1999-2000, 2000-01 to 2009-10, and 2010-11 to 2019-20, respectively.

Revenues have increased only slowly, compared to the increase in other large emerging markets (Figure 2). Between 1980-81 and 2022-23, tax revenue rose by 3.3 percentage points of GDP, reflecting tax buoyancy (elasticity of revenues with respect to income) only slightly above 1. Non-tax revenue, which includes interest and dividends, has similarly remained stagnant as a proportion to GDP. The elasticity of revenues with respect to income is higher in other large middle-income economies, with the sole exception of Indonesia.<sup>4</sup> In comparison, the expenditure-to-GDP ratio has been close to

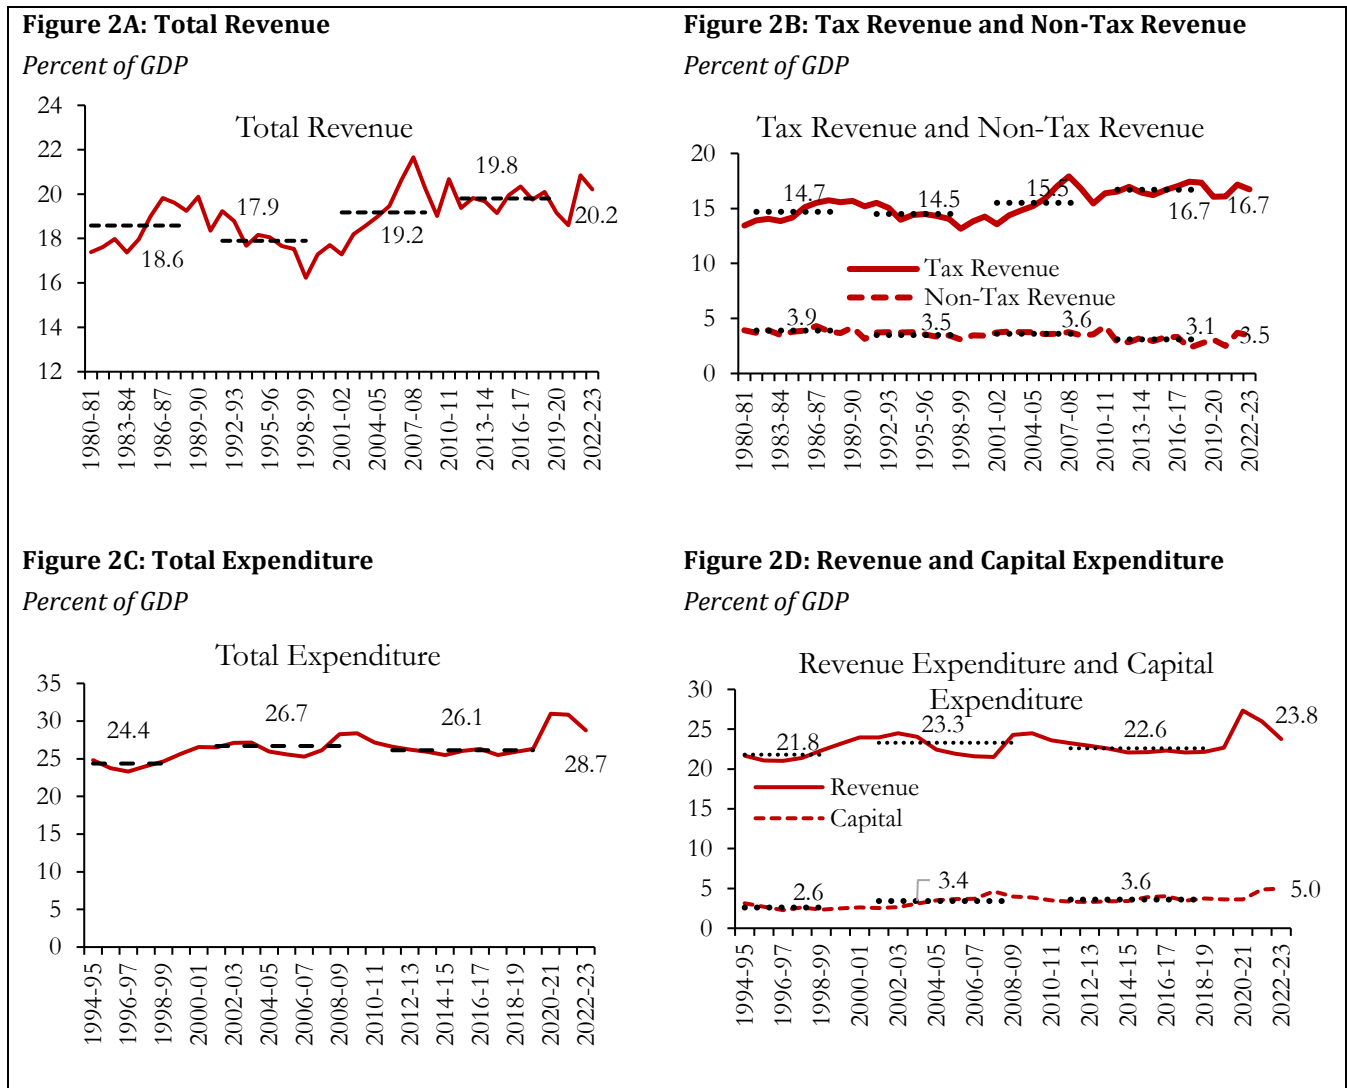

<sup>3</sup> Total Public Debt in India includes debt issued and other liabilities in Public Account consisting of National Small Saving Fund (NSSF), Provident Fund, Deposit and Reserve funds, securities issued to finance subsidies on oil, food, and fertilizers, etc.

<sup>4</sup> Whereas direct tax collection has increased in proportion to GDP, indirect taxes as a proportion of GDP have declined, indicating a tax buoyancy of more than 1 for direct taxes, and less than one for indirect taxes (Appendix A).

the median of other emerging countries. This gap has resulted in a perennially large, and even increasing, budget deficit compared to other emerging markets.

Expenditure overall has remained broadly stable for two decades, the only large increase occurring during COVID. Nearly 85 percent has been revenue or committed expenditures.<sup>5</sup> Capital spending has been low, rising modestly from 2.3 percent of GDP in 1994-95 to 3.6 percent of GDP by 2011-12, and hovering close to that level over the period 2020-21. It then rose by 1.4 percentage points to 5.0 percent of GDP in the past two years, reflecting the government's infrastructure push.

**Figure 2: General Government (Federal and States) Revenue and Expenditure**

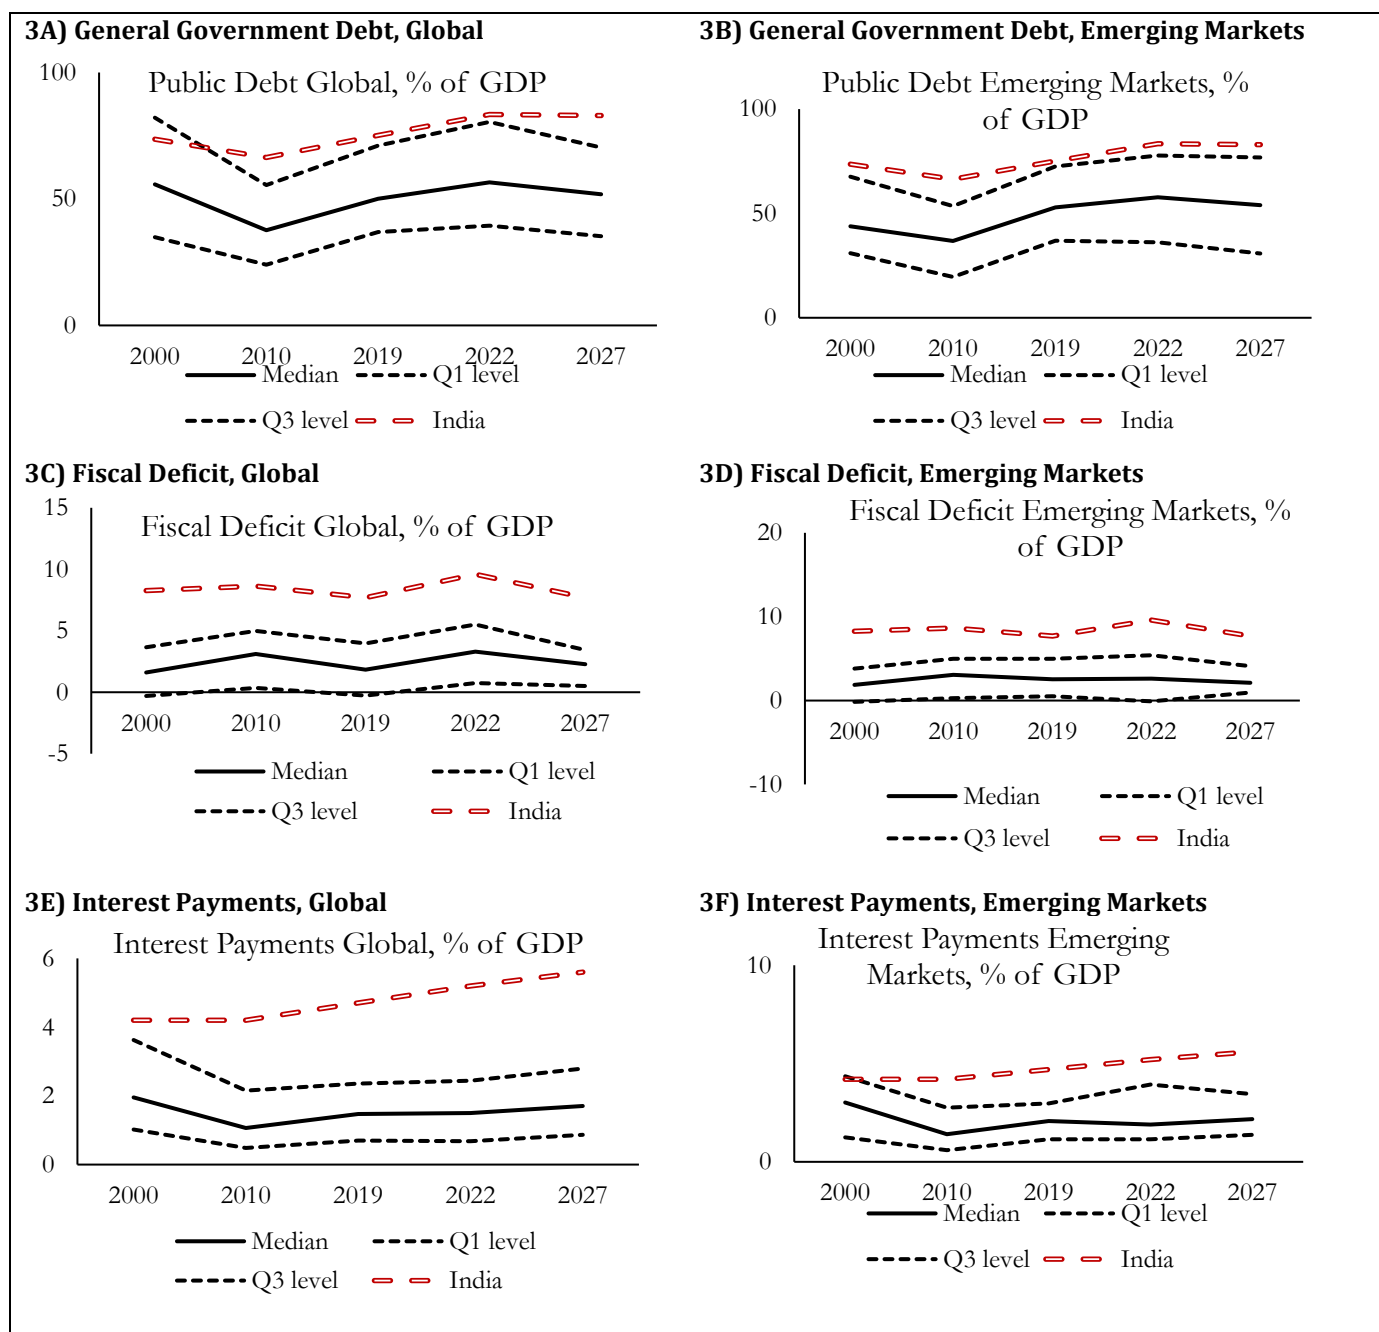

Source: CEIC (Compiled from Reserve Bank of India). Dashed horizontal lines are decadal averages from 1980-81 to 1989-90, 1990-91 to 1999-2000, 2000-01 to 2009-10, and 2010-11 to 2019-20, respectively.

Interest payments are high by global and emerging market standards (Figure 3). The IMF (2023) projects a further rise in the interest-payments-to-GDP ratio over the 2023-27 period as global rates trend upward.

<sup>5</sup> Revenue expenditures are expenditures incurred for purposes other than the creation of physical or financial assets. They are incurred for the normal functioning of the government departments, interest payments, and grants to State governments and other parties.

While India's debt ratio is comparable or lower than in the advanced economies, this is scant comfort. Advanced-country governments enjoy lower interest rates and consequently have lower interest-payment-to-GDP ratios. Debt-to-GDP ratios of advanced economies averaged 112 percent in 2022, whereas interest payments averaged 1.5 percent of GDP. In contrast, India pays as much as 5 percent of GDP in interest on debt.

**Figure 3: Comparing India's Fiscal Indicators with Other Country Averages (General Government)**

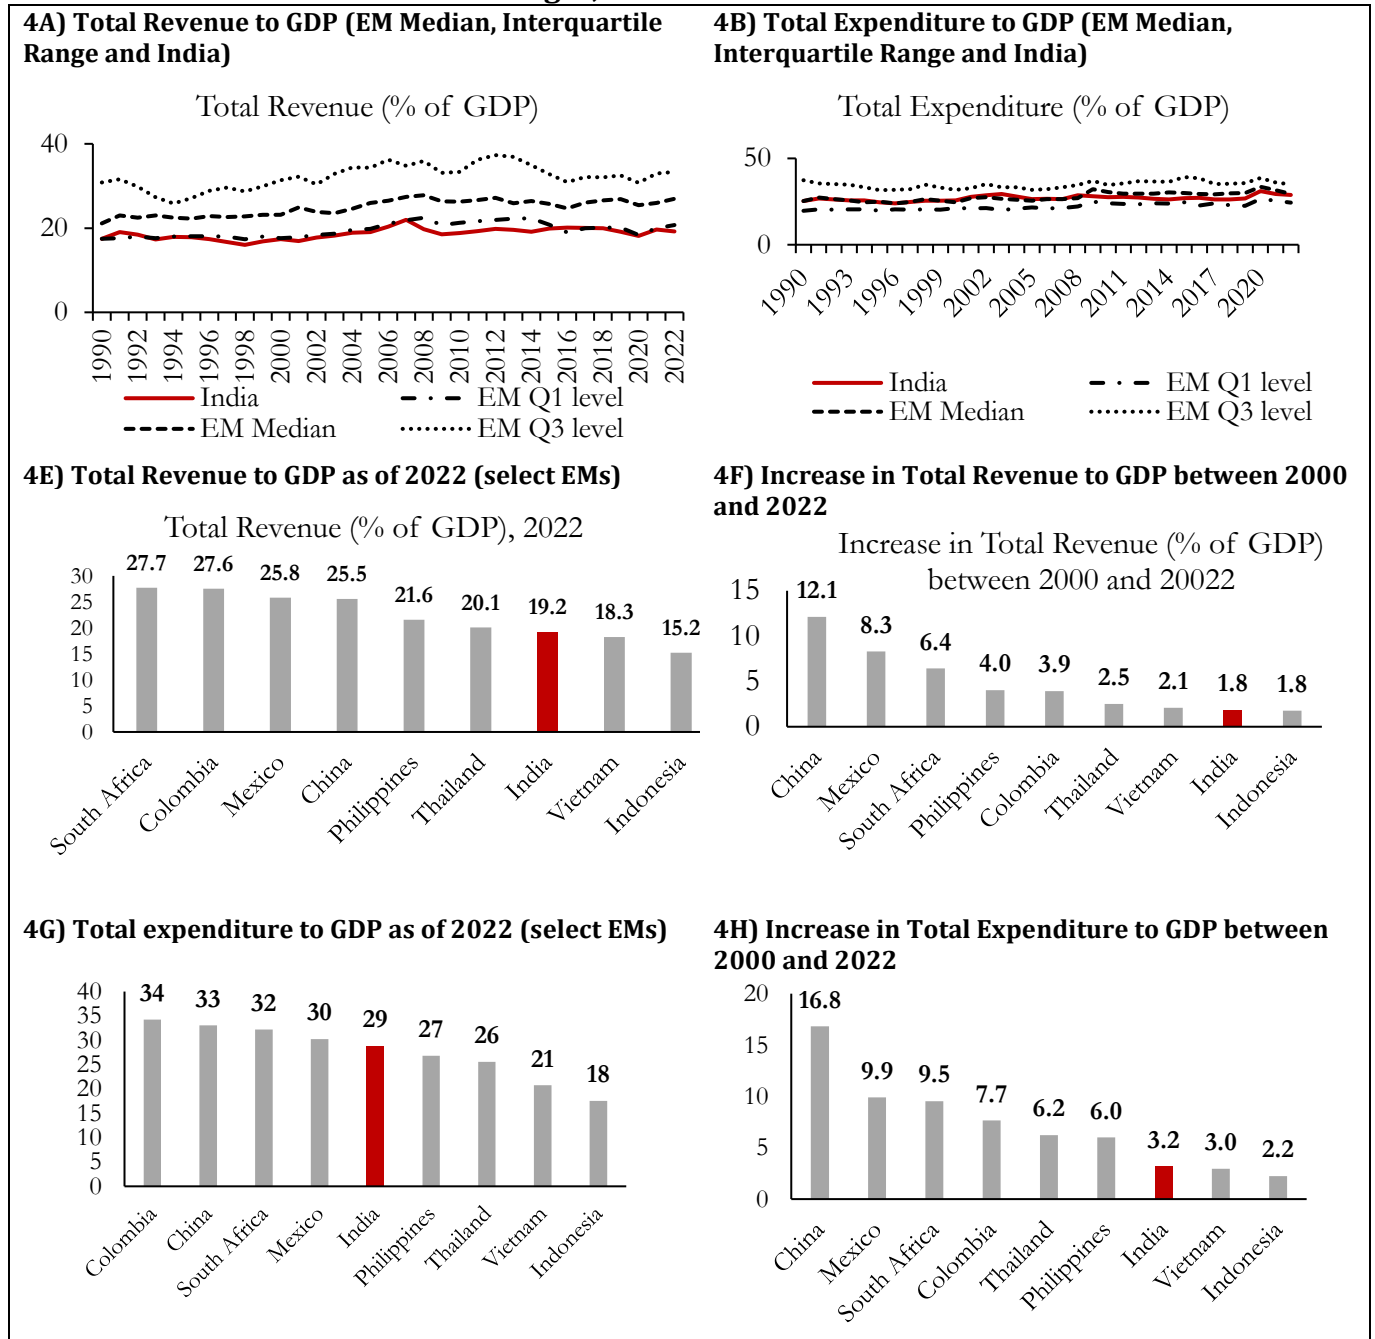

Source: Fiscal Monitor Database, IMF April 2023. Figures show median and interquartile range of the respective variables and respective country or country groups.

Figure 4 shows that the revenue-to-GDP ratio is below that of most other emerging markets (see also Rao 2018). Not only is the level below that in other countries, but India has one of the slowest rates of increase over the last 20 years. In contrast, the public-expenditure-to-GDP ratio is not atypical and, if anything, has increased more slowly. India's deficit is evidently more a problem of low revenues than one of high expenditure.<sup>6</sup>

**Figure 4: Comparing India's Fiscal Indicators with Emerging Market (EM) Averages, General Government**

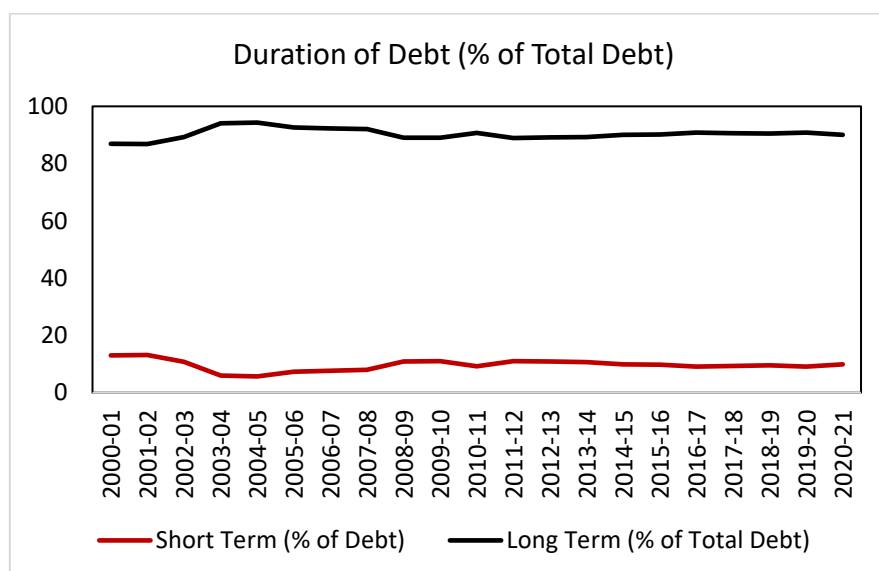

Source: Fiscal Monitor, IMF April 2023. Figures 4A and 4B show median and interquartile range of Emerging Market and Middle-Income Economies (83 countries) and India. Data for India is for fiscal years.

<sup>6</sup> We return to this point in Section 5 below.

### 3. Debt Composition

Nearly 90 percent of General Government debt is long-term, as measured by residual maturity (Figure 5).<sup>7</sup> There has been a concerted effort to reduce rollover risk by issuing long-tenor securities. As a result, the weighted average maturity periods for both Central and State government loans have been increasing (Figure 6).

**Figure 5: Duration of Debt (General Government)**

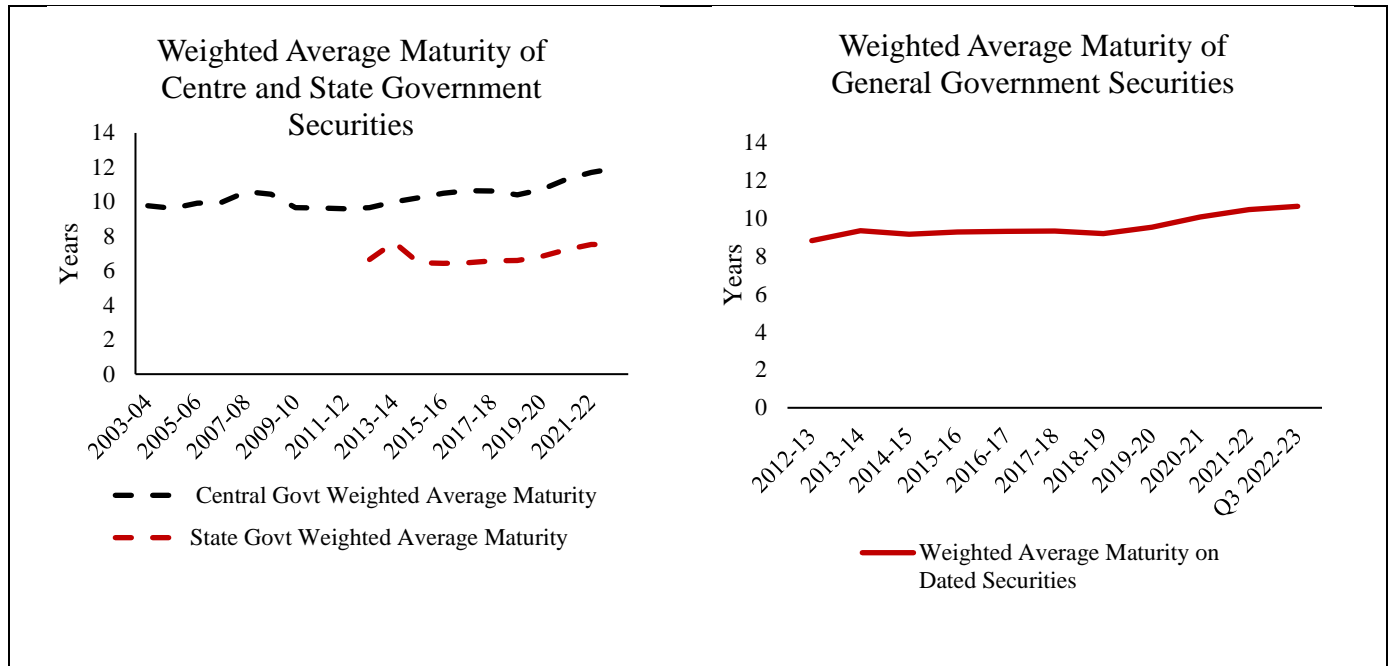

*Source:* Data for short-term debt for 2000-01 to 2009-10 are from Status Paper, Ministry of Finance, September 2016; and then from Status Paper on Government Debt, Ministry of Finance, April 2022. Long-term debt is calculated as total minus short-term debt.

Tenors vary. The share of Central Government debt with a maturity greater than 20 years rose from 13 to 20 percent between 2012 and 2021. In the two most recent years, a majority of debt issued by the Central Government has had a maturity of 14 years or longer, and 30 percent has had a 30- or 40-year maturity.

State debt has a lower average maturity. As of March 2022, about 5 percent of the outstanding State Development Loans (SDLs) had a maturity of less than a year. Maturity periods for 30 percent of SDLs were 1-5 years, for 45 percent 5-10 years. The remaining 20 percent had a maturity of 10 years or longer (of which a small proportion had a maturity of more than 20 years).<sup>8</sup> The market for long term debt is thin, and the term premium for all but the highest quality borrowers (insurance companies and the like) can be significant. The States seek to minimize interest costs; they therefore issue shorter-term debt while waiting for the market in longer-term debt to develop further.

<sup>7</sup> Short-term debt of the Center includes 14-day intermediary treasury bills, 91-day, 182-day, and 364-day treasury bills, dated securities maturing in the ensuing year, and external debt with residual maturity of less than one year. For the states, short-term debt includes market loans maturing within the next year, loans to the Center due in the ensuing year, and short-term borrowings from the RBI through Ways and Means Advances (WMA).

<sup>8</sup> According to the RBI's Report on State Finances (January 2023), "Though 63.3 per cent of the outstanding State government securities is in the residual maturity bucket of five years and above, redemption pressure is expected to remain high till 2030-31."

**Figure 6: Weighted Average Maturity of Outstanding Debt**

*Source:* For the Center, Status Papers (April 2022 and September 2016), Ministry of Finance, from 2003-04 to 2020-21, Public Debt Management Quarterly Report, RBI (March 2023) for 2021-22 and Q3 2022-23; For state governments: Monthly Reviews of the Economy, Clearing Corporation of India (CCIL). GDP Deflator is from the Economic & Political Weekly Research Foundation (EPWRF).

*Note:* We use the shares of the Center and states in total debt as weights to calculate weighted average maturity on the General Government outstanding stock, for Q3 2022-23, the shares are assumed to be the same as those for 2021-22. For Q3 2022-23, the weighted average maturity is the average of the weighted average maturities for the period Q1-Q3 2022-23.

While the average maturity of public debt has risen, yields have declined, if slightly. The General Government weighted average coupon fell from 8 percent in 2011-12 to 7.3 percent in 2022-23 (Figure 7). The average yield on Central Government debt has been slightly lower than that on State debt.

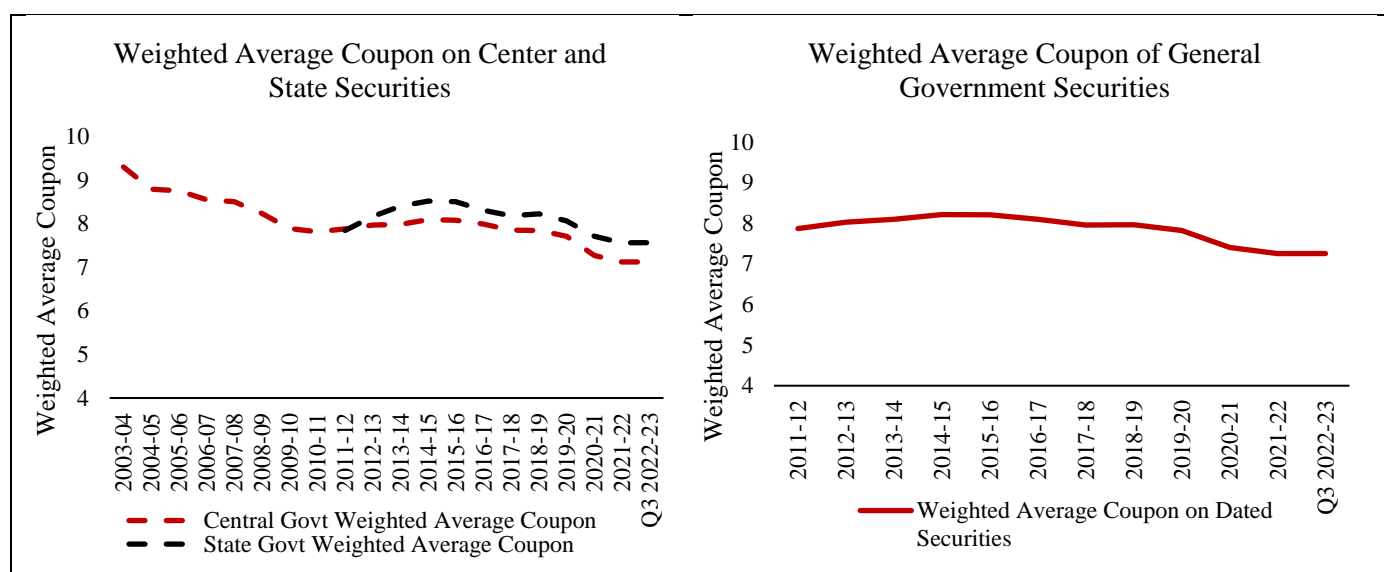

Strikingly, bond yields in India have not moved with the level of indebtedness or inflation. This is true at both the Central and State Government levels. Moreover, the interest rate at which different States raise their debts does not vary significantly by the level of indebtedness, primary deficit, or the rate of economic growth.<sup>9</sup> Mishra and Patel (2018) suggest that this reflects an implicit guarantee from the central government, and the fact that the largest investors in government bond markets (public sector banks, insurance companies and provident funds) are owned by the Central Government, and as such are not purely profit maximizing entities. These institutional investors are all required to hold government bonds as a statutory requirement (see Appendix C below).

In addition the Reserve Bank of India (RBI), by carefully scheduling the calendar of borrowing and coaxing government-owned investors to hold the bonds of the States, ensures that interest rates on State debt remain in a tight range. Evidently, it does not want perceptions of debt distress or unsustainability of the debts of some States to

<sup>9</sup> The calculations are based on the average nominal weighted average yield on new issues.

infect others. We are not convinced of the advisability of this policy; we will have more to say about it below.

**Figure 7: Cost of Debt (Outstanding Debt)**

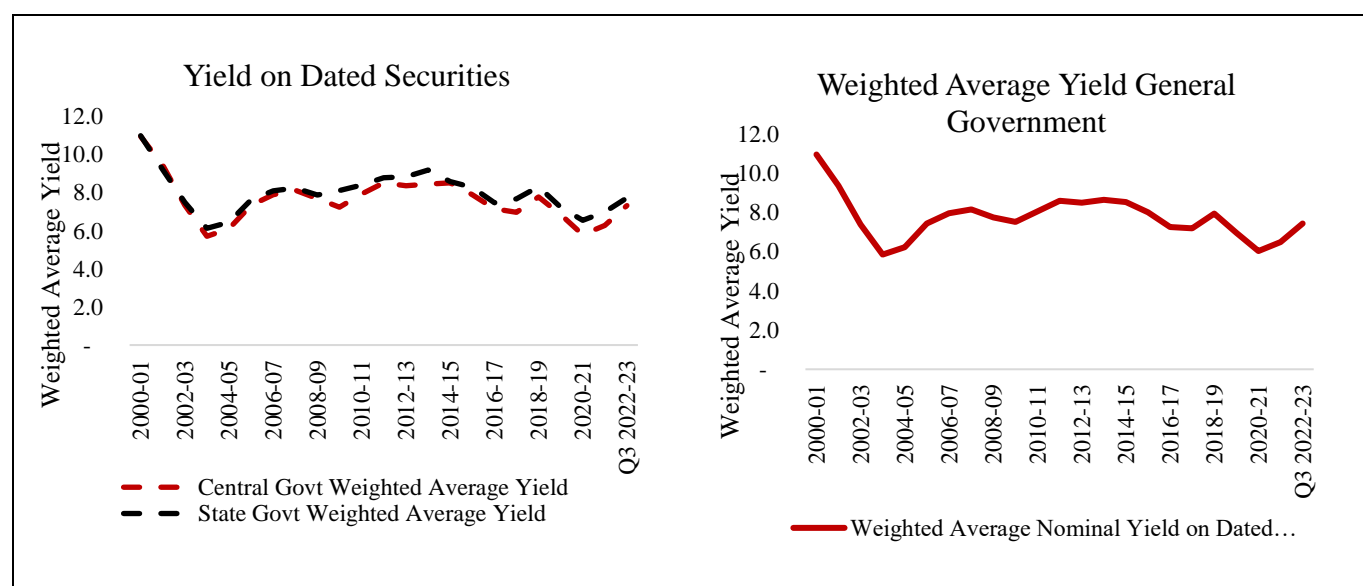

*Source:* For the Center Nominal WAC: Status Papers (April 2022 and September 2016), Ministry of Finance, from 2003-04 to 2020-21, Public Debt Management Quarterly Report (March 2023) for 2021-22 and Q3 2022-23. For State Nominal WAC: Monthly Review of the Economy, Clearing Corporation of India (CCIL).

*Note:* The shares of the Center and States in total debt are used as weights to calculate the weighted average coupon on General Government outstanding stock.

The average yield on new issuances has also declined over time, from about 11 percent in 2000-01 to about 7.5 percent currently (Figure 8).

**Figure 8: Cost of Debt (new issues in the year)**

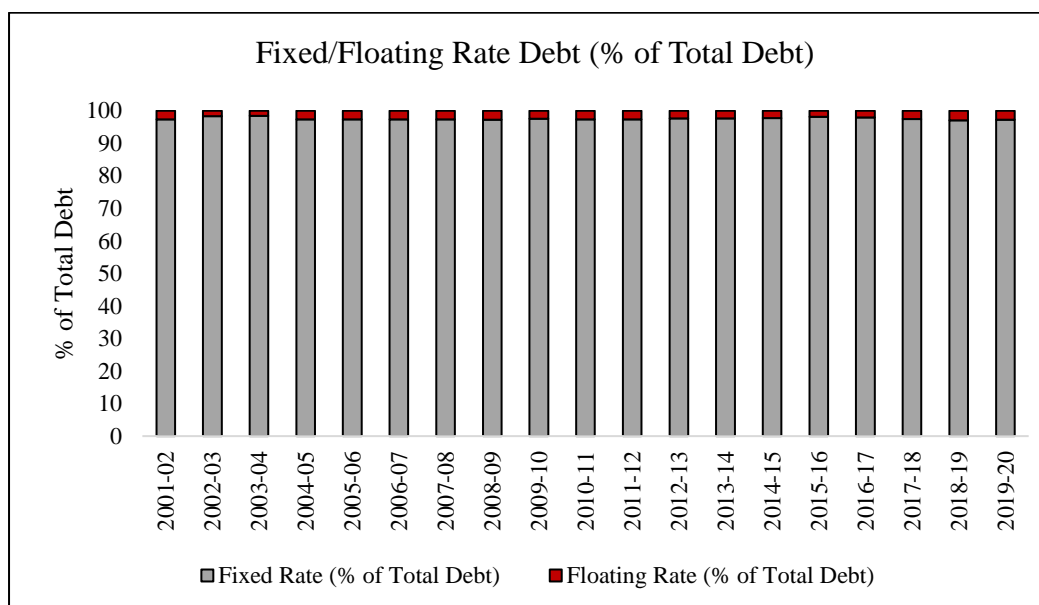

*Source:* For the Center and State WAY, RBI (till 2020-21). For the Center, Public Debt Management Quarterly Report (March 2023) for 2021-22 and Q3 2022-23; and for the State: State Finances Report (2023), RBI, for 2021-22 and 2022-23. Yield is for primary issues in the year indicated.

*Note:* Shares of the Center and States in total debt are used as weights to calculate the Weighted Average Yield (WAY) on General Government primary issues (new issues in the year).

As Figure 9 shows, less than 4 percent of General Government debt in 2020-21 is offered at floating rates. (Only the Central Government offers floating debt.<sup>10</sup>) Thus, the country's debt portfolio is largely insulated from short-run interest rate volatility.

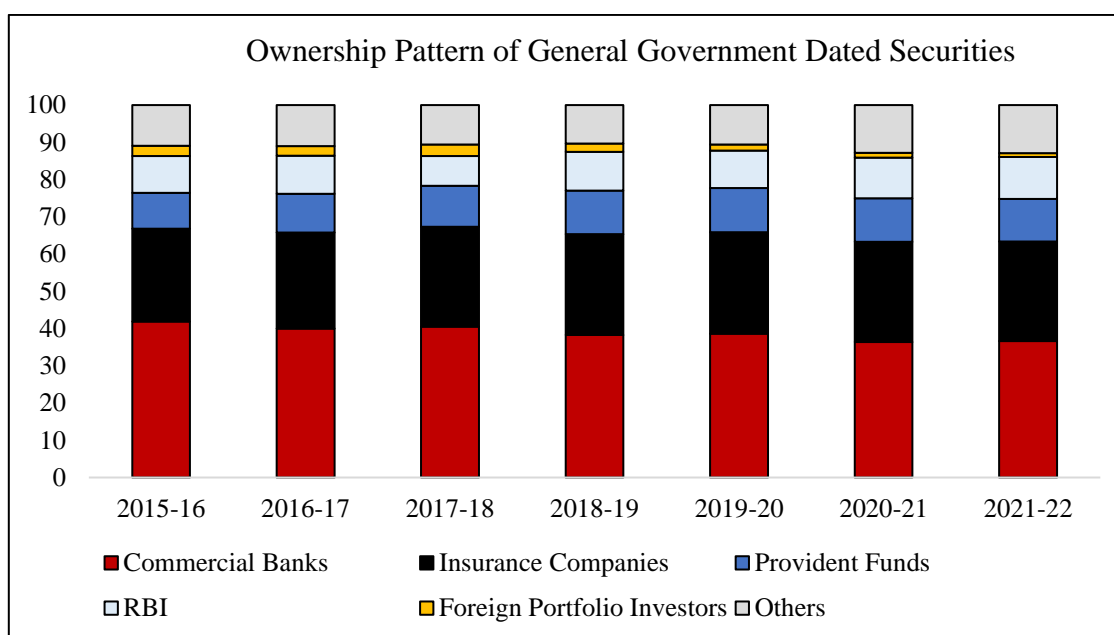

**Figure 9: Fixed and Floating Rate Debt**

*Source:* Data for years 2000-01 to 2009-10 is from the Status Paper (September 2016); data for 2010-11 to 2020-21 are from the Status Paper (April 2022), Ministry of Finance.

Figure 10 shows the proportion of General Government debt securities in different hands. In 2015-16, about 42 percent of General Government debt was owned by commercial banks. The bank share then dropped to 37 percent in 2021-22, as various regulatory requirements mandating their holding government bonds were relaxed (see below, including Appendix D). Foreign portfolio investors owned about 3 percent of public debt securities in 2015-16; their share similarly dropped to 1 percent in 2021-22. Correspondingly, the shares of insurance companies, provident funds and the RBI increased over time.

<sup>10</sup> A floating rate bond is based on a benchmark rate, such as the repo rate, reverse repo rate, treasury bill yield, or saving schemes interest rates, plus a fixed spread that is determined at the time of first issuance.

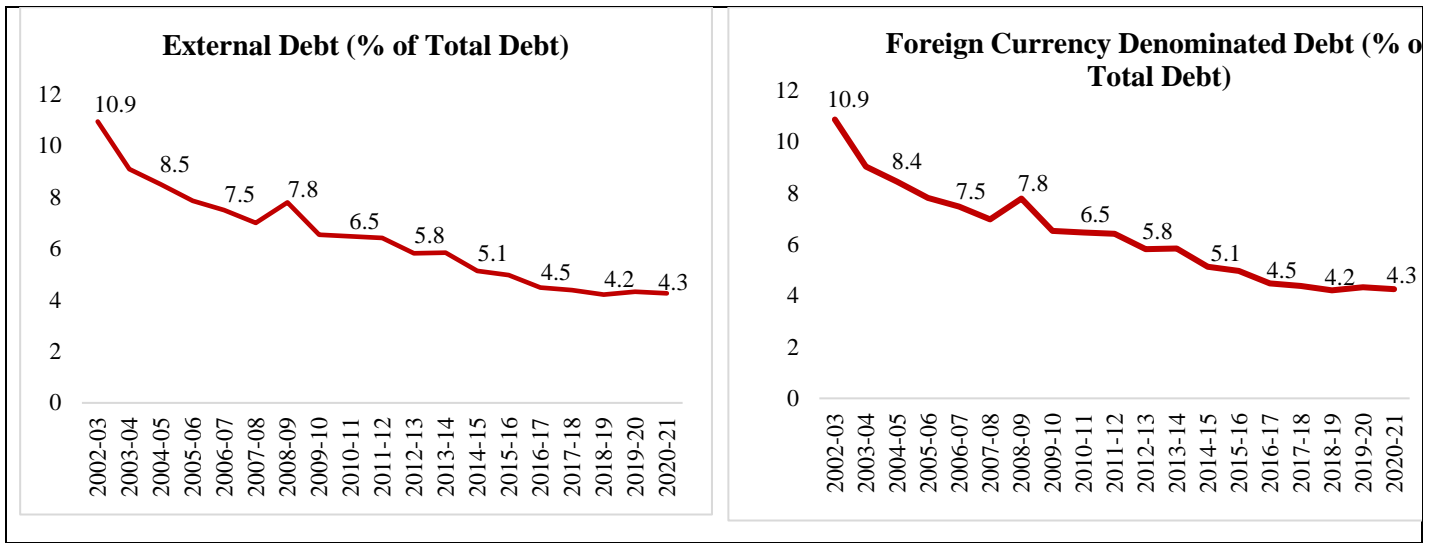

**Figure 10: Ownership of Debt**

*Source:* Public Debt Statistics, RBI. Note: Provident funds are retirement funds run by the government. Others include Co-operative Banks, Non-Bank PDs, Mutual Funds, Corporates, Financial Institutions, and Others.

In 2000-1, about 13.5 percent of Central Government debt was issued externally. Since then there has been a steady decline in the share of external debt, which stood at just 3.7 percent in 2021-22 (Figure 11). The remainder is long-term instruments, concessional, and owed to multilateral and bilateral investors (amounting to 3 percent of the total debt)<sup>11</sup> Holdings of foreign institutional investors are just 1 percent of the total debt. Foreign banks hold negligible quantities of Indian government debt.

As is to be expected, most of this externally-held debt is denominated in foreign currency. Debt denominated in foreign currency dropped from about 10 percent of the total in 2002-03 to 4.3 percent in 2020-21 (Figure 11). Consequently, the debt portfolio is largely insulated from currency risk.

<sup>11</sup> In 2003-04, IDA was the largest source of multilateral external debt. Since then, its share has dropped by half (from 54 percent of the external debt to 26 percent in 2021), with a corresponding increase in debt from IBRD and ADB, which contributed to 16 percent and 19 percent of the external debt, respectively, as of 2020-21. Among the bilateral sources, Japan has consistently been the largest contributor, accounting for 24 percent of the external debt in 2020-21, followed by Germany and Russia.

**Figure 11: External Debt (% of Total Debt), General Government**

Source: Status Paper on Government Debt (September 2016), Ministry of Finance, for the data for 2002-03, and Status Paper on Government Debt (April 2022), Ministry of Finance, for the data from 2003-04 to 2020-21. Note: External debt is debt to foreign lenders: banks, nonbank financial institutions, international organisations and foreign governments, among others.

#### 4. Debt Sustainability

We now use extrapolations of the debt/GDP ratio as a way of thinking about debt sustainability. We use Equation 1 to project the trajectory of public debt.<sup>12</sup>

$$\Delta b_t = \frac{b_{t-1}(r_t - g_t)}{1 + g_t} + pd_t \quad (1)$$

Here  $b_t$  is the debt-to-GDP ratio,  $pd_t$  is the primary-deficit-to-GDP ratio (deficit net of interest payment),  $g_t$  is growth of real GDP, and  $r_t$  is the real interest rate on public debt; all in year  $t$ .  $\Delta b_t$  is the change in debt-to-GDP ratio between  $t$  and  $t-1$ .

#### General Government

We consider a baseline scenario and several additional scenarios. As the baseline, real GDP growth, the real interest rate, and the primary deficit will be at the same levels for the next five years as their respective averages from 2013-14 to 2022-23 (Table 2) – that is, 5.7 percent, 2.8 percent and 2.9 percent, respectively.<sup>13</sup> This yields an annual increment to the debt/GDP ratio of 0.5 percentage point a year, implying a cumulative increment of 2.2 percentage points over five years. General Government debt is projected to reach 88.7 percent of GDP in 2027-28 (Table 3).

<sup>12</sup> The exercise is based on the assumption that  $g$ ,  $r$ , and  $pd$  are exogenous, that is, they are not impacted by the level of debt.

<sup>13</sup> For comparison, in 2022-23 growth was 7.0 percent, the real interest rate was -1.0 percent, and the primary deficit was 3.7 percent.

The second scenario assumes faster GDP growth. Our third scenario then adds a favorable change of half a standard deviation in the primary deficit from the average level over the past decade for each variable (Table 3). Thus, we assume GDP growth of 7.9 percent a year, or a primary deficit of 1.9 percent, respectively.

In this second scenario, the debt/GDP ratio declines by 1.2 percentage points a year, reaching 81.0 percent in 2027-28. In the third scenario, it declines by 0.5 percentage points a year, reaching 83.9 percent in 2027-28.<sup>14</sup> Thus, even under optimistic assumptions, the debt/GDP ratio will remain high relative to comparator countries.

The debt ratio will also remain high relative to India's Fiscal Responsibility and Budget Management (FRBM) targets, which foresee a debt-to-GDP ratio of no more than 60 percent.<sup>15</sup> But adherence to these targets is not mandatory. There is no formal mechanism to monitor compliance, and there are no penalties for breaching the targets. It follows that governments have not been able to adhere to these limits on deficits and debts.

**Table 1: Average Values and Standard Deviations of the Key Parameters for General Government**

	<b>Ten-year average (2013-14 to 2022-23)</b>		<b>Five-year average (2018-19 to 2022-23)</b>	
	Mean	Std dev	Mean	Std dev
Nominal GDP growth ( $\gamma$ )	10.7	4.3	4.1	5.9
Deflator growth ( $\pi$ )	4.7	2.3	5.6	2.7
Real GDP growth ( $g$ )	5.7	5.3	10.0	7.9
Nominal interest rate ( $i$ )	7.5	0.8	7.0	0.7
Real interest rate ( $r$ )	2.8	2.6	1.4	2.9
Primary deficit ( $pd$ )	2.9	2.1	4.0	2.6
Growth-interest differential ( $g-r$ )	3.0	4.8	2.7	7.2

<sup>14</sup> We obtain similar pathways for public debt under most other reasonable scenarios.

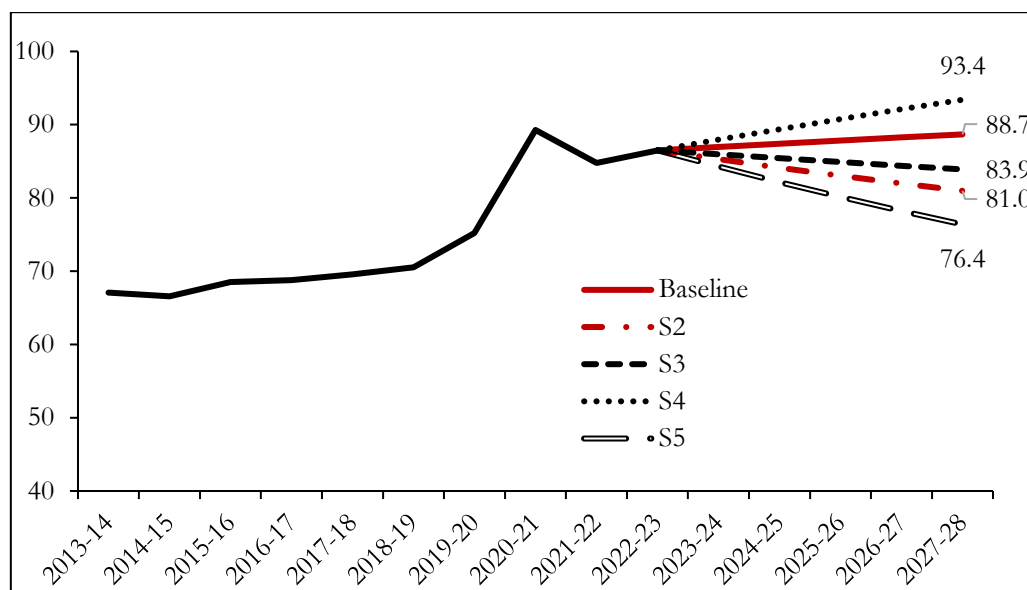

<sup>15</sup> The Sarma Committee on Fiscal Responsibility Legislation was set up in 2000 to recommend fiscal reforms. After several rounds of reviews and modifications, its deliberations led to the formulation of the Fiscal Responsibility and Budget Management Act. In 2016, a committee under N.K. Singh was then tasked with suggesting changes in the Act. It suggested using General Government debt as the primary target for fiscal policy, with a General Government debt-GDP target of 60 percent to be achieved by 2023 (40 percent for the Centre and percent for the States). Accordingly, the Finance Act of 2018 included the following amendments to the FRBM Act. First, the fiscal deficit should be reduced to 3 percent of GDP by 2020-21. Second, the revenue deficit (the difference between recurrent expenditure and recurrent earnings) and effective revenue deficit (revenue deficit minus any grants that the states received from the Center for capital expenditure) were no longer targeted. Third, General Government debt again was not to exceed 60 per cent of GDP, while Central Government debt was not to exceed 40 per cent of GDP, but now by the end of 2024-2025.

**Table 2: Evolution of General Government Debt-to-GDP Ratio**

Scenarios	Scenario Description	Debt level in 2022-23 ( $b_{t-1}$ )	Primary Deficit (pd)	Real GDP growth (g)	Real Interest Rate (r)	Change in Debt in first year ( $\Delta b_t$ )	Cumulative Change in Debt in next five years
Baseline (S1)	Baseline: Past 10-year averages	86.5	2.9	5.7	2.8	0.5	2.2
S2	Higher real GDP growth rate	86.5	2.9	7.9	2.8	-1.2	-5.5
S3	Lower Primary Deficit	86.5	1.9	5.7	2.8	-0.5	-2.6
S4	S1 plus contingent liabilities absorbed (1 percentage point of GDP) each year	86.5	2.9	5.7	2.8	1.5	6.9
S5	S1 with Higher real GDP growth rate and Lower Primary Deficit	86.5	1.9	7.9	2.8	-2.2	-10.1

Note: Projections start from 2023-24. For 2022-23, estimates of the level of debt are from the *Economic Survey*.

**Figure 12: Evolution of General Government Debt-to-GDP Ratio under Different Scenarios**

Note: The estimate of debt for 2022-23 has been taken from Chapter 3 of *Economic Survey 2022-23*.

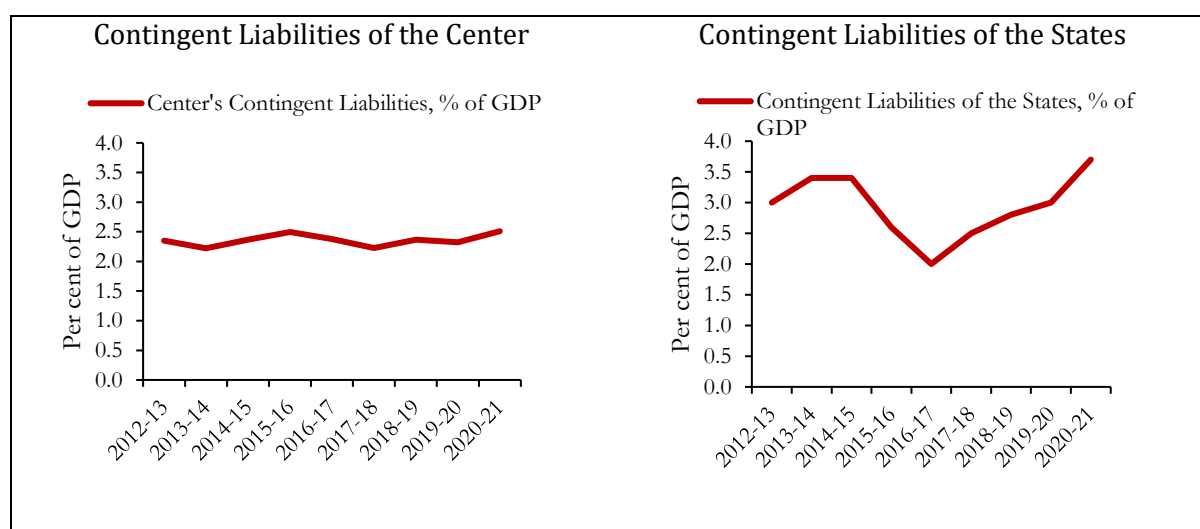

The RBI in its reports on state finances and the IMF in its Article IV Reports warn of the impact of contingent liabilities on debt sustainability. RBI (2023) observes that “State government guarantees increased sharply by end-March 2021, which has implications for their debt sustainability.” IMF (2022a) reports that “[f]iscal risks reflect higher macroeconomic uncertainty, particularly from the external sector, and contingent liabilities from public sector banks and electricity generation corporations.” Past contingent liabilities have been on account of Air India, public sector banks, electricity distribution companies, public-private partnerships (PPPs) in infrastructure

provision, and other state-owned enterprises (SOEs). They materialized when governments assumed the debts of companies, rescuing and recapitalizing them. Blanchard et al. (2021) apply Equation 1 to historical data for India and take the difference between actual and implied changes as the realization of contingent liabilities. They find these to have been substantial. Alternatively, the Office of the Comptroller and Auditor General and RBI have attempted to estimate contingent liabilities directly; as of March 2021 they put these at 2.5 percent of GDP for the Central Government and 3.7 percent of GDP for the States (Figure 15).

We assume that contingent liabilities will be taken onto the budget at a rate of one percentage point of GDP each year for the next five years. Unsurprisingly, this will add another 6.9 percentage points of GDP to the debt, taking it above 93 percent of GDP under baseline assumptions.<sup>16</sup>

The bottom line is that even under an exceptionally favorable scenarios, General Government debt to GDP is unlikely to decline below 80 percent on current policies. And less benign scenarios are possible.

**Figure 13: Contingent Liabilities**

Source: Financial Audit Reports on Account of Union Government, CAG, Union Budget Statements, and RBI.

**Table 3: GDP-Growth-Rate-Interest-Rate Differential and Accumulation of Public Debt**

	Average g-r	Average Primary Deficit	Debt Level in 1981-82	Debt Level in 2019-20	Change in Debt-to-GDP
1981-82 to 2019-20	1.9	2.9	48.8	75.7	26.9

<sup>16</sup> Were such liabilities instead taken onto the budget at a rate of two percentage points of GDP, this would straightforwardly add 13 percentage points of GDP to the debt, and so forth.

### Central Government

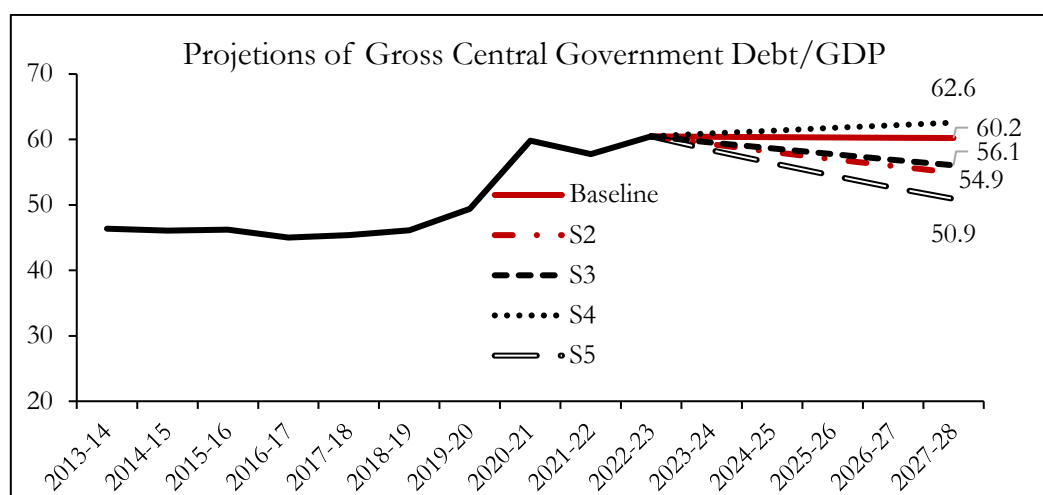

We use Equation 1 to project public debt for the central government in scenarios similar to those for General Government. In the baseline, for the next five years GDP growth, the real interest rate, and the primary deficit will be at the same levels as their respective averages from 2013-14 to 2022-23 (5.7 percent, 2.6 percent and 1.7 percent; see Table 4). This yields a stable debt-to-GDP ratio (actually, a small reduction of about 0.3 percentage points over the period, as shown in Table 5). In the second scenario where we assume faster GDP growth, debt to GDP declines by a cumulative 5.6 percentage points. A similar reduction is projected in the third scenario of a lower primary deficit. The only scenario in which the debt of the central government is projected as rising relative to GDP is when contingent liabilities materialize.

**Table 4: Average Values and Standard Deviations of the Key Parameters for Central Government**

	Ten-year average (2013-14 to 2022-23)		Five-year average (2018-19 to 2022-23)	
	Mean	Std dev	Mean	Std dev
Nominal GDP growth ( $\gamma$ )	10.7	5.3	10.0	7.9

## State Governments

For purposes of projection, we take the debt-to-GDP ratio, growth of nominal GDP, rate of inflation, and growth of real GDP as identical for the Center and the States. However, primary deficits and interest rates differ (Table 6). In most scenarios including in the baseline, the debt-to-GDP ratio of the States is projected to increase (Table 7). By implication, the projected increase in General Government debt can be primarily (even entirely) attributed to the increase in debt to GDP ratio of the States.

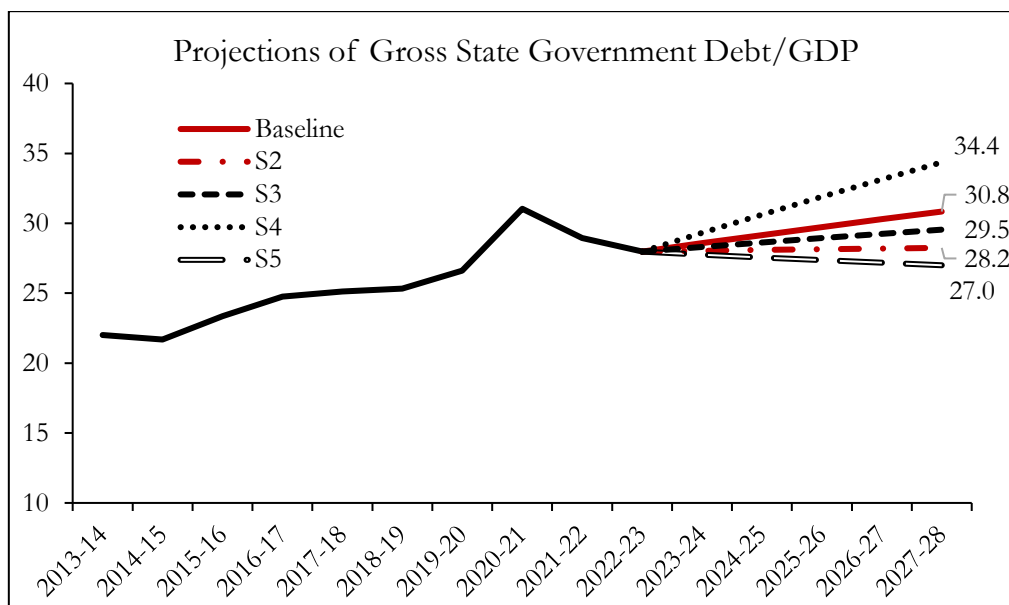

The contrast reflects higher interest rates. States pay about 0.5 percent higher interest than the Center. As a result,  $g-r$  is less favorable. This is why the States' debt has accumulated faster than the Center's despite lower primary deficits.

**Table 6: Average Values and Standard Deviations of the Key Parameters for State Government**

	Ten-year average (2013-14 to 2022-23)		Five-year average (2018-19 to 2022-23)

**Figure 15: Evolution of the State Government's Debt-to-GDP Ratio**

Source: State Finances Report, RBI (2013-14 up till 2022-23). State debt refers to Total Outstanding Liabilities of States including loans and advances from the Central Government. Projections are for 2023-24 onwards.

A few states such as Gujarat and Maharashtra have managed their public finances well.<sup>17</sup> Their debts have increased least since 2014-15, remaining below 25 percent of state GDP (Table 8). At the other end of the spectrum are Punjab, Rajasthan, and Kerala, whose debts have increased on average by 12 percentage points of GDP since 2014-15 and exceeded 40 percent of state GDP at the end of 2020-21.

Maharashtra	18.1	18.1	20.9	0	2.8

*Note:* GDP refers to the GDP figures of the respective States.

We compare some key variables across these two sets of States in Table 9. We define a dummy variable that equals 1 for States with an above-median increase in debt to GDP, and 0 for those below the median.<sup>18</sup> The results show that States with large increases in debt ratios had primary deficits and contingent liabilities more than twice those of States with small increases. Although they also had slightly slower GDP growth, this differential was not significant. Inflation and interest rates did not differ across the

<sup>17</sup> In this section, we focus on the 18 largest Indian states. Erstwhile Special Category States and the Union Territories are not included.

<sup>18</sup> Similar results are obtained if instead of comparing the States which are below and above the median we compare the values of these variables for the top one-third of the States for the increase in debt-to-GDP ratio with the bottom one-third of the States.

two classes of States. Recall how we noted the absence of an interest rate differential above.

**Table 9: Comparing States with a Large Increase in the Debt-to-GDP Ratios with Those with a Smaller Increase in the Debt-to-GDP Ratio**

	(1) Real GDP Growth	(2) Inflation	(3) Nominal Interest Rate	(4) Primary Deficit GDP	(5) Capital Expenditure to GDP	(6) Contingent Liabilities to GDP	(7) Debt to GDP

Constant	6.01*** (12.67)	3.40*** (14.13)	7.67*** (225.9)	0.91*** (5.38)	4.17*** (10.27)	1.94* (2.34)	26.79** *(11.4)
No. of observations	18	18	18	18	18	18	18

*Note:* Median change in the debt to GDP ratio in 2014-15 and 2020-21 is 11.1. The dummy takes a value 1 for states where the increase in the debt-to-GDP ratio between 2014-15 and 2020-21 exceeded 11.1, and a value 0 for the states with a below median increase. Variables are averaged over the period. Inflation is the rate of growth of the state-specific GDP deflator. t statistics are in parentheses \*, \*\*, \*\*\* refer to significance at 10, 5, and 1 percent levels, respectively.

In Tables 10-12 and Figures 16-17, we present debt sustainability analyses for Punjab and Gujarat, states representative of those with high and low debt/GDP ratios. Debt is unlikely to stabilize and may even increase further in Punjab. In Gujarat, on the other hand, debt is projected to decline as a share of state GDP in all scenarios.

In sum, States in a less favorable position are likely to face graver problems of debt sustainability, owing to slower economic growth, larger contingent liabilities, and higher interest rates for States overall. Given projections of a stable debt-to-GDP ratio for the Central Government, the behavior of these problem States constitutes the main threat to debt sustainability.

A question is why these problem states have had so much room to run. One answer is that, as we have already noted, borrowing costs do not vary across States. Despite different debt levels (and different projected primary deficits and contingent liabilities), Gujarat and Punjab issue at equivalent interest rates. This reflects the RBI's efforts to equalize interest rates across States.<sup>19</sup> De facto, this results in States in better fiscal health subsidizing those whose health is worse. It relaxes market discipline on errant States.

<sup>19</sup> We have not found much scholarly literature on this issue. Practitioners have pointed us to the following: (1) SDLs of different states are all eligible for the RBI's repo facility subject to the same haircut; (2) banks are allowed to mark to market different states' SDLs identically; (3) all SDLs held by banks carry zero risk weights; (4) the RBI provides states with short term loans up to a specified percentage of its borrowing needs; (5) at the end of the day SDLs are covered by a broader central bank and government guarantee. Verifying these hypotheses and identifying their relative importance is an important topic for future research.

The horizontal devolution of taxes among States, awarded by the Finance Commission (FC) every five years, also does not provide incentives for fiscal rectitude.<sup>20</sup> FCs are mandated to allocate more resources to States with larger revenue deficits, which is an obvious source of moral hazard. The 15<sup>th</sup> FC included tax effort (the ratio of per capita own tax revenue to per capita state GDP in the previous three years) as one criterion in its larger devolution matrix, but this did not solve problems on the expenditure side. Some States keep significant expenses and liabilities off budget. FCs do not have data, mechanisms, or a clear mandate to estimate contingent liabilities. The 15<sup>th</sup> FC was asked to recommend performance incentives for States in areas like the power sector and solid waste management. But FCs have not been asked to consider overall fiscal prudence or contingent liabilities (except indirectly through reforms of the power sector) when recommending allocations.

FCs are dissolved immediately after they report to the President. There is no parallel institution or body to monitor States' finances and assess whether they have departed from the course projected by the FC. Thus, it would be desirable to establish a permanent Fiscal or Expenditure Council to monitor state finances, assess the quality of data and forecasts, and inform the public of the fiscal stance and debt sustainability of different States.<sup>21</sup>

**Table 10: Average Values and Standard Deviations of the Key Parameters for Punjab**

	<b>Ten-year Average (2013-14 to 2022-23)</b>		<b>Five-year Average (2018-19 to 2022-23)</b>	
	Mean	Std dev	Mean	Std dev

Contingent Liabilities as % of GDP	8.9	7.0	3.6	2.4

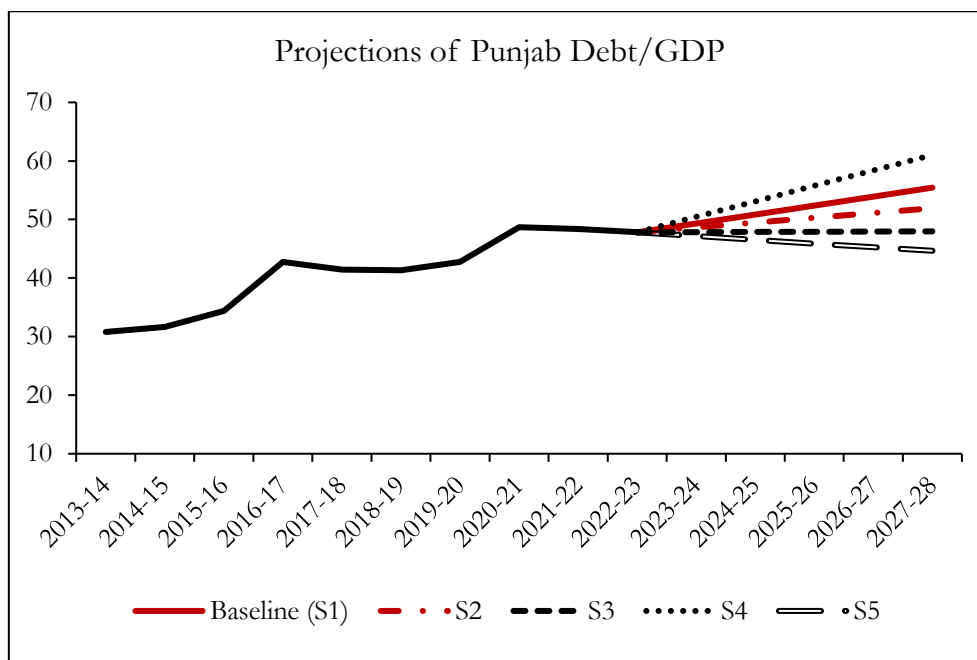

<sup>20</sup> The Finance Commission (FC) is a constitutional body formed by the President of India every five years to recommend the devolution of revenue to the States and its horizontal distribution. The sixteenth FC is slated to be announced later in 2023-24. An earlier literature (von Hagen and Eichengreen 1996) suggests that vertical fiscal imbalances (where the center raises taxes but states are responsible for spending programs) provide states with incentives to run larger deficits, in the expectation of consequently receiving larger transfers from the center. To the extent that tax reforms have located more revenue-raising capacity at the center, this vertical fiscal imbalance and associated deficit bias may have grown more acute.

<sup>21</sup> See Rao (2018) on Fiscal Council and Debroy and Sinha (2023) on Expenditure Council.

## 5. Sharp Reductions in Debt

We focus now on past episodes of debt consolidation. We define consolidations as episodes when the general government debt ratio fell consistently for at least five consecutive years. Using data starting in 1990, this yields two consolidation episodes: 1991-92 to 1997-98; and 2004-05 to 2012-13. Debt reduction was 6.7 percent of GDP in the first episode, 16.9 percent in the second.<sup>22</sup>

The first episode followed a balance-of-payments crisis during which India signed up for an IMF program.<sup>23</sup> The IMF loan was conditioned on fiscal consolidation designed to reduce the Central Government's deficit from 8.5 percent of GDP in 1990-91 to 5 percent in 1992-93 (Chopra and Collins 1995). This decline was premised on lower recurrent and capital expenditure. Inflation accelerated (the average annual rate of GDP inflation was about 10 percent), reflecting exchange rate depreciation in 1991-92.<sup>24</sup> Consolidation proceeded despite the fact that growth was slower than in control years, and despite the fact that tax revenues also grew more slowly.

2004-05 to 2012-13, in contrast, was marked by faster growth, especially between 2004-05 and the Global Financial Crisis. Tax and administrative reforms yielded dividends in the form of higher revenues. In this second episode unlike the first, the decline in the primary deficit was underpinned by higher tax revenue rather than by lower expenditure; capital expenditure, in particular, was protected.

<sup>22</sup> This is in contrast to Eichengreen and Esteves (2022), who also required the debt ratio to fall by at least 10 percentage points in order for it to qualify as a consolidation episode.

<sup>23</sup> India signed the IMF program agreement in October 1991 and exited it in June 1993.

<sup>24</sup> The exchange rate was first sharply devalued from its artificially appreciated levels, and was later floated (managed float).

Of the reduction of 17 percentage points in the debt to GDP ratio, nearly 10 points were accounted for by the States. These initiatives by State Governments were supported by a Debt Swap Scheme (DSS) in 2002-03/2004-05 and a Debt Consolidation and Relief Facility (DCRF) in 2005-06/2009-10. Under DSS, States could prepay expensive loans from the Central Government and instead raise cheaper loans from the market. Under DCRF, debt relief was provided to the states through debt reduction, rescheduling of debt and lower interest rates, conditional on enacting and implementing Fiscal Responsibility and Budget Management legislation. Debt relief was linked to the improvement in fiscal performance (assessed in terms of the reduction in revenue deficits). This experience is a reminder that debt consolidation at the State and Central Government levels is not independent; the Central Government can play an important role in providing incentives to the States.

**Table 14: Episodes of Debt Consolidation**

Consolidation	Duration (Years)	Initial Debt	Terminal Debt	Change in debt to GDP ratio ( $\Delta b_t$ )
1991-92 to 1997-98	7	74.2	67.5	-6.7
2004-05 to 2012-13	9	83.6	66.7	-16.9

In Table 15 we regress a set of outcome indicators on a dummy variables equaling 1 in years of debt consolidation, defined as above, and 0 otherwise. The results show that inflation is more than twice as high during consolidation episodes, while the primary deficit is about 1 percentage point lower. Higher inflation might be thought to make for a lower real interest rate, but the real interest rate is significantly lower than in the control-group years only in the second consolidation episode, when its low level was largely attributable to the low level of nominal rates post-Global Financial Crisis. On average, growth is not significantly different than in normal (non-consolidation) years.

**Table 15: A Comparison of Key Variables during the Consolidation Episodes and Normal Years**

	(1) Inflation	(2) Growth	(3) Real Interest Rate	(4) Nominal Interest Rate	(5) Real Growth - Real Interest Rate	(6) Primary Deficit
Dummy =1 for 1991-92 to 1997-98	4.49*** (4.44)	-0.48 (0.37)	-0.20 (0.18)	4.29*** (6.17)	-0.28 (0.18)	-1.14* (1.63)

*Note:* Data are from 1990-1991 to 2022-2023. t statistics in parentheses. \*, \*\*, \*\*\* refer to significance at 10, 5, and 1 percent levels, respectively.

Table 16 compares total revenue, tax revenue, total expenditure, and capital expenditure across consolidation episodes and normal years. While the primary deficit was lower in both episodes compared with control years, its reduction was achieved in different ways. In 1991-92/1997-98, a lower primary deficit was attained by compressing expenditure, including capital expenditure. The consequences were not growth friendly. In the second episode, in contrast, the decline in primary deficit was obtained mainly through higher revenue collection, including by raising tax revenue. The result was at least growth neutral.

**Table 16: A Comparison of Key Variables during the Consolidation Episodes and Normal Years**

	(1) Total Revenue	(2) Tax Revenue	(3) Total Expenditure	(4) Capital Expenditure
Dummy =1 for 1991-92 to 1997- 98	-0.75 (1.54)	-1.13** (2.18)	-1.64** (2.22)	-0.74** (2.01)
Dummy=1 for 2004-05 to 2012- 13	1.08** (2.42)	0.79* (1.67)	-0.33 (0.49)	0.30 (1.09)
Constant	18.91*** (71.98)	15.67*** (56.24)	26.95*** (67.57)	3.42*** (20.83)
No. of Observations	33	33	33	29

*Note:* Data are from 1990-1991 to 2022-2023. Capital expenditure data is available from 1994-1995 onwards. t statistics are in parentheses. \*, \*\*, \*\*\* refer to significance at 10, 5, and 1 percent levels, respectively.

In sum, consolidation is easier when debt is reduced by both the Center and the States. Contrary to assertions in the literature (Alesina, Favero and Giavazzi 2019), it is not obvious that consolidations achieved by cutting spending has worked better than consolidations achieved by raising revenues. The Alesina et al. result is obtained from data for advanced countries, where spending and taxes are arguably too high. As we showed above, international comparisons suggest that tax revenues are too low in India (not that spending is too high). This is a reminder of the need to tailor advice to context.

In neither case was it possible to maintain the lower levels of debt achieved in the consolidation episode. In both cases more than half the reduction was reversed subsequently. After the 7 percentage point reduction in debt/GDP from 1991-92 to 1997-98, debt rose from 68 percent of GDP in 1998-99 to 85 percent in 2003-04, more than fully reversing its preceding fall. Debt rose despite an acceleration in GDP growth from 5.3 percent to 5.9 percent per annum. This rise was attributable to an increase in primary deficit from 2 percent to 3.3 percent and to some decline in inflation that translated into higher real interest rates.

The reduction of debt achieved from 2004-05 to 2012-13 was partially reversed in 2013-14/2019-20, when the debt ratio rose from 67 percent to 75 percent. The period was marked by the same primary deficit ratio as in the preceding consolidation

period, a slight deceleration in growth (from 6.9 percent to 6.7 percent), and once more a fall in inflation that translated into higher real rates.

These post-consolidation experiences speak to the limited role of inflation in debt consolidation. It is tempting to think that a country whose debt is at long tenors can inflate away a significant portion. Inflation was higher during both consolidation episodes than in other periods, consistent with this presumption. Inflation worked to reduce debt, especially in the second of the two episodes, by helping to depress the real interest rate. But once the burst of inflation passed and inflation came down, this effect was reversed. Arslanalp and Eichengreen (2023) analyze annual data on inflation and debt for a panel of countries stretching to 1800. They estimate the relationship using local projections and simulate the effect of an inflation shock. Consistent with what we find here for India, they show that the impact of an inflation shock on the debt ratio is temporary. That impact effect is reversed over time as interest rates, maturities and spending begin to adjust.

## 6. Costs and Risks

What are the costs and risks of India's high debt and deficits? In the introduction to our paper we identified five.

First, interest payments absorb resources, limiting their availability for other economic and social purposes. Interest payments exceed 25 percent of general government revenues. This share is roughly twice the emerging market and developing-country average. At 5 percent of GDP, they are again twice the emerging market average (Figure 3 above). This difference reflects not high borrowing costs but rather high levels of debt. In contrast, government expenditure as a share of GDP is in line with other emerging markets. With interest payments absorbing a larger share of revenues, less is left for other needs. As noted above, the government spends more on interest than on education and health combined. Its interest payments exceed its capital expenditure.

Second, and relatedly, available fiscal resources leave no room for meeting emerging priorities, notably climate change abatement and adaptation and the green transition. McKinsey (2022) estimates that, owing to its exposed geography, India will have to invest half as much again as advanced economies as a share of GDP to maintain its economic development in the face of climate change and in order to build low-carbon infrastructure. According to its Net Zero 2050 scenario, India will have to spend 11 percent of GDP between now and 2050 on decarbonization and low-carbon growth, compared to the global average of 7.5 percent. This reflects elevated heat exposure of urban residents in particular, as well as the need for extensive spending on low-emissions assets and enabling infrastructure. Not all of this investment must be financed by government revenues and borrowings, of course. Global investment funds, oil and gas majors, foreign utilities, Indian conglomerates, government companies, and pension funds are all taking equity stakes in Indian renewable energy projects (Jaiswal and Gadre 2022). Wind and solar power companies issue debt to finance their investments, borrowing from domestic and international banks and development finance institutions. In 2019-21 some 50 percent of their debt financing is sourced overseas, a growing share in the form of green bonds. This said, regulatory risk (changes in tariffs and rates), planning risk (mis-estimation of power generation

capacity) and extreme weather risk (including from climate change) make a significant public-finance contribution unavoidable.

Third, debt dynamics leave little room for responding to shocks, such as declining rates of domestic and global growth. India was not strongly constrained in responding to COVID-19; it reacted with a fiscal stimulus of 20 trillion rupees, or roughly 9 percent of GDP. About a third of this was above-the-line measures (spending on social protection and health care and foregone revenues); the remaining two thirds of below-the-line measures involved various forms of business support (IMF 2022b). The combined response, while smaller than in the advanced economies (Hudson et al 2022), was nonetheless substantial. Mishra and Patel (2022) argue that the resulting increase in debt has put upward pressure on interest rates, although our own analysis fails to find much evidence of this (see Appendix C). Be this as it may, at some point responding in this way to shocks will begin to show up in interest rates, especially as regulations encouraging investments in bonds by insurance companies, provident funds and banks are progressively relaxed. At some point, this will begin to throw debt sustainability into doubt. Conversely, maintaining debt sustainability in the face of such shocks will leave the government countercyclically constrained, amplifying cycles.

Fourth, high government debt creates the potential for financial stability risks. For the moment, such risks remain limited.<sup>25</sup> Banks are required to hold government securities in order to satisfy their Statutory Liquidity Ratios (SLR); they are required to hold liquid assets, including government bonds, of a specified minimum percentage of deposits.<sup>26</sup> Risks to their balance sheets can therefore develop with the repricing of these assets when interest rates rise. But SLR has been cut from 38 percent in the early 1990s to 18 percent in recent years (see Appendix D). As a result, banks now hold a smaller share of their assets in government securities. The RBI has also mandated that banks hold highly liquid assets as Investment Fluctuation Reserves (IFR), intended as a buffer against fluctuations in their investment portfolios. As of December 2022, banks held more than the mandated level of reserves. Moreover, public sector banks are no longer more exposed to interest rate risk than private banks or foreign banks. All this has limited portfolio repricing risk, though by no means eliminating it.

But this reduction in mandated bank holdings means, in turn, that government is relying on a more diverse set of investors to hold its debt. The share of insurance companies, provident funds and other non-bank investors in Central Government securities has increased from 20 percent in 1990-91 to 46.6 percent in 2021-22 (as noted earlier).<sup>27</sup> For the moment, insurance companies and provident funds are required by regulation to hold roughly 50 percent of their investable funds in government securities. But if regulations compelling the insurance companies and provident funds to hold government bonds are further relaxed and/or domestic savings decline, Central and State governments will be forced to place additional debt, including

---

<sup>25</sup> Such is our judgment. In addition, the RBI in its biannual Financial Stability Reports does not flag the holding of government securities, or changes in the interest rate, as significant risks to Indian banks.

<sup>26</sup> Business Standard, Aug 16, 2022, notes some of the developments which have led to a decline in the interest rate risk for the Indian banks: [https://www.business-standard.com/article/finance/banks-now-in-better-position-to-manage-rbi-s-interest-rate-risks-122081601071\\_1.html](https://www.business-standard.com/article/finance/banks-now-in-better-position-to-manage-rbi-s-interest-rate-risks-122081601071_1.html)

<sup>27</sup> The RBI also holds a larger fraction of public debt than in the past. The RBI's share has increased from 7.8 percent of the Central Government debt in 2007-08 to 16.6 percent in 2021-22. The corresponding numbers are smaller for the General Government.

short-term debt, with foreign investors, in the manner of other emerging markets. If externally-held debt is denominated in foreign currency, as in other countries, this will increase the sector's currency mismatch, creating debt-servicing and financial difficulties when exchange rates move. Even if India succeeds in placing rupee-denominated debt with foreign investors, this nevertheless raises the risk of a capital-flow reversal, an investor strike and a bond-price collapse, since the currency mismatch will now be on foreign balance sheets, encouraging foreign investors to flee at the first sign of trouble (Carstens and Shin 2019).

For the moment, India may be able to place most of its debt with “patient” domestic investors. But if this becomes less true going forward, run risk – and volatility – will rise.

## 7. Conclusion

Our central conclusion is that India's general-government-debt-to-GDP ratio, which is high by emerging market standards, is unlikely to decline significantly in the next five years. In the best-case scenario, it might fall from its current level of some 90 percent of GDP, which is half again as high as the emerging market average, to 80 percent of GDP, where it would be 30 percent again as high. But less rosy scenarios are also possible.

What might be achieved with more ambition? In purely mathematical terms, India could bring down its debt to 70 percent of GDP through a combination of lower primary deficits, higher inflation, and faster GDP growth. A percentage point increase each in growth and inflation and a percentage point reduction in the primary deficit would reduce public debt to 70 percent of GDP in five years. The requisite changes could be achieved through an amalgam of the following factors:

- Raising additional revenue through higher tax, non-tax, and privatization receipts. Along with better tax administration and digitalization, recent tax reforms have succeeded in boosting revenue growth. Yet in a fast-growing economy, where nominal GDP has been growing on average at 11-12 percent, the rate of tax-revenue growth still has not exceeded that of GDP growth, in contrast to other fast-growing emerging markets.
- Continuing to re-orient spending toward capacity- and infrastructure-enhancing investment that promises to further boost GDP and revenues.
- Limiting contingent liabilities, which have been a chronic problem at the state level.

But imagining sharp changes along these lines borders on wishful thinking. Meanwhile, economic and social development will require additional spending on health and education. Government will have to contribute significantly to the country's decarbonization and climate-change-adaptation investments, which are large by international standards. Eventually, interest rates will adjust upward in response to inflation, eliminating any favorable debt-consolidation effects. As a result of these factors, India will almost certainly be living with high public debt for years to come.

All this said, the country faces no immediate crisis of debt sustainability. Our baseline scenario does not point to exploding debt ratios. For the moment, rollover risk is limited. Most public debt securities are held by banks, insurance companies and

other patient domestic investors. It is denominated in rupees. Little is at short maturities or floating rates.

But the preceding does not mean that the country's relatively high public debt is without costs. Devoting a large share of financial resources to servicing debts leaves the Central Government and States with fewer resources for other investments. At some point, it will leave less room for responding to shocks. Even if volatility is limited now, this could change with financial liberalization and deregulation. The bottom line is that India's high public debt leaves no room for missteps.

## Appendix A

**Table A.1: Data**

Indicator	Source
Total Liabilities of General Government	1. CEIC. Estimate for 2022-23 has been taken from Chapter 3 of the <i>Economic Survey 2022-23</i> . We have used the words debt and liabilities interchangeably in the paper.
General Government Primary Deficit	Calculated as the difference between Fiscal Deficit and Interest Payments
General Government Interest Payments, Total Revenue, Tax Revenue, Non-Tax Revenue, Total Expenditure, Revenue Expenditure, Fiscal Deficit	CEIC
Data for the center and the state governments	For key fiscal variables, we considered data from RBI (Handbook of Statistics on Indian Economy), State Finances Report, RBI, CEIC Database, Economic Survey, and India Series in the Economic and Political Weekly Research Foundation's (EPWRF) Database. While largely data for Center and State Government match across these sources (with EPWRF's estimates slightly different than those provided by RBI and CEIC), the data for debt does not add up to General Government Data. We calculated Centre's debt as the difference between General Government Outstanding Liabilities and State's Outstanding Liabilities net of loans and advances from the Centre. For the other variables, we used the RBI's Database on Indian Economy and its State Finances Report.
General Government Debt for Global and Emerging Markets	Fiscal Monitor, IMF April 2023
General Government Fiscal Deficit for Global and Emerging Markets	Overall balance of General Government, Fiscal Monitor, IMF April 2023
Interest Payments on General Government Debt for Global and Emerging Markets	Calculated as the difference between fiscal deficit and primary deficit, compiled from the Fiscal Monitor, IMF April 2023
Contingent Liabilities	The data for contingent liabilities is available from 2008-09 till 2021-22 for the Central government and has been compiled from various annual financial audits of the union government conducted by the CAG. The outstanding guarantees data for states is available from 1991-92 onwards and is published by the State Finances Report. The data for Centre's outstanding guarantees and state's outstanding guarantees are available for 2008-09 to 2021-22 to get the general government contingent liabilities.

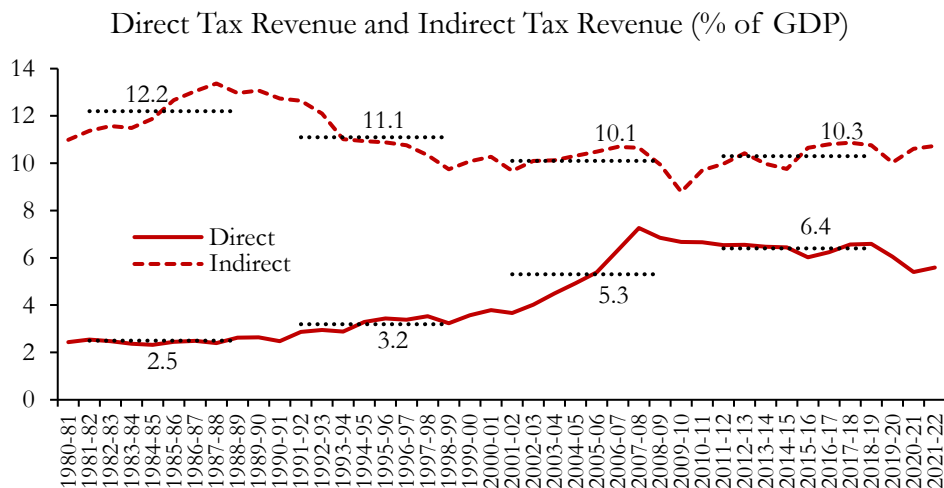

## Appendix A: Tax Buoyancy

Figure A.1: Tax Buoyancy

*Source:* Author's calculations. Note: Tax buoyancy is measured as the ratio of tax revenue growth relative to nominal GDP growth for each of the years shown in the chart. If gross tax receipts increase more than proportionally to an increase in nominal growth (that is, the ratio is greater than 1), then we say that the tax system is buoyant. Horizontal dashed lines are for decadal averages from 1981-82 to 1989-90, 1990-91 to 1999-2000, 2000-01 to 2009-10, and 2011-12 to 2019-20.

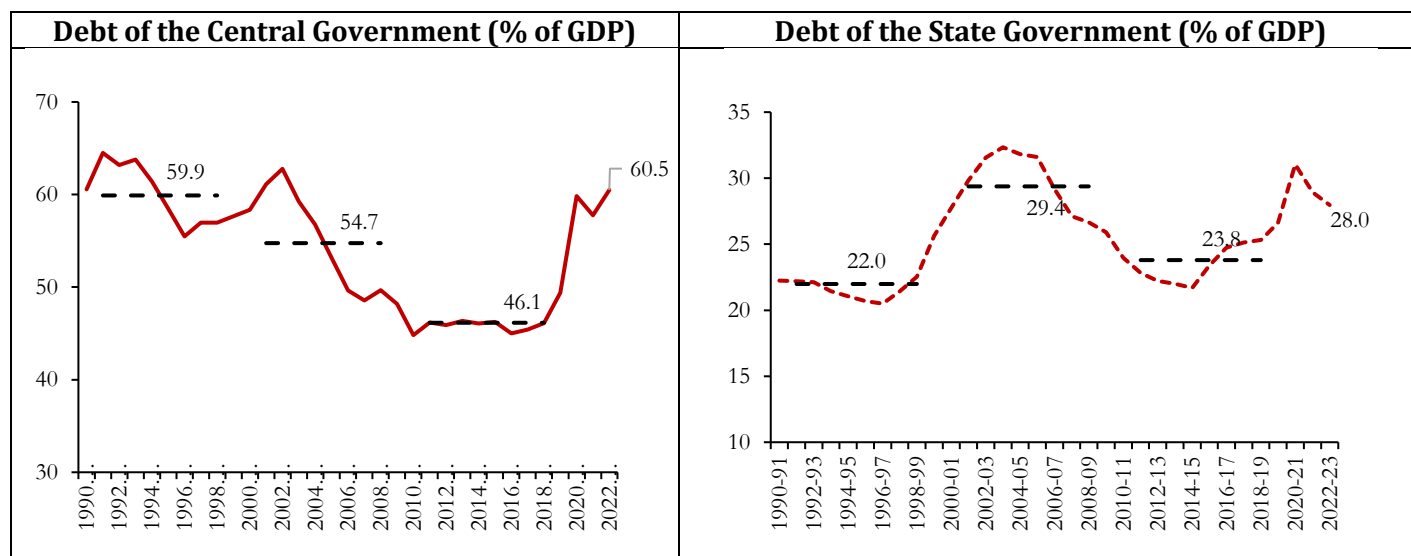

Figure A.2: Direct and Indirect Taxes

*Source:* RBI. Direct taxes refer to taxes levied on property or income such as income tax and personal property tax. Indirect taxes refer to. Indirect taxes are levied on goods and services such as GST and customs and excise duties. The data for 2020-21 is a Revised Estimate and for 2021-22 is a Budget Estimate. Horizontal dashed lines are for decadal averages from 1981-82 to 1989-90, 1990-91 to 1999-2000, 2000-01 to 2009-10, and 2011-12 to 2019-20.

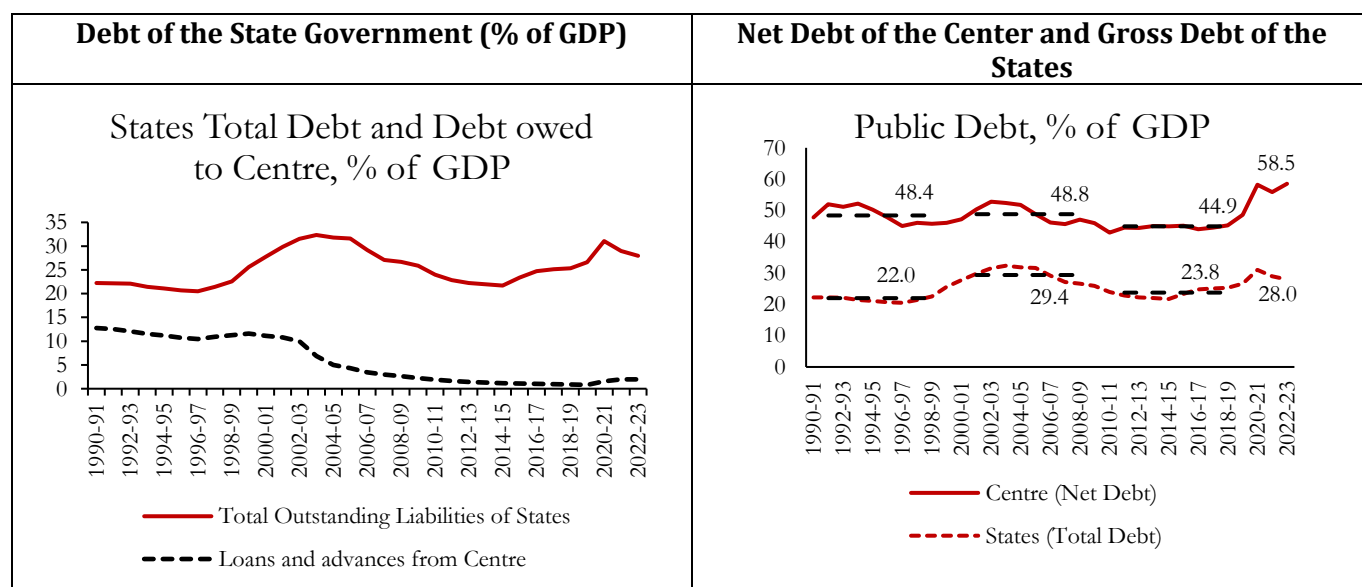

## Appendix B: Debt and Deficit of the Center and the States

**Figure B.1: Public Debt of the Central and State Governments**

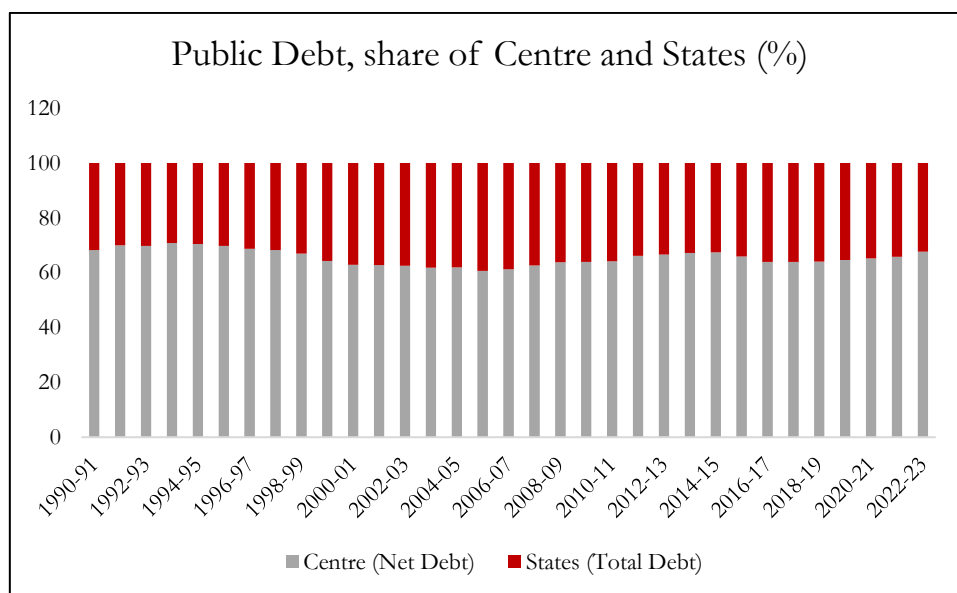

Source: State Finances Report, RBI (States). For 2021-22: Revised Estimates and for 2022-23 the Budget Estimates for State's Total Debt. The charts show the total outstanding liabilities of Central Government and State Government as % of GDP. States total liabilities include the debt it owes to the Centre. Centre's Total Debt has been calculated as the difference between general government total outstanding liabilities and state government liabilities net of loans and advances from the Centre. Horizontal dashed lines are the respective decadal averages.

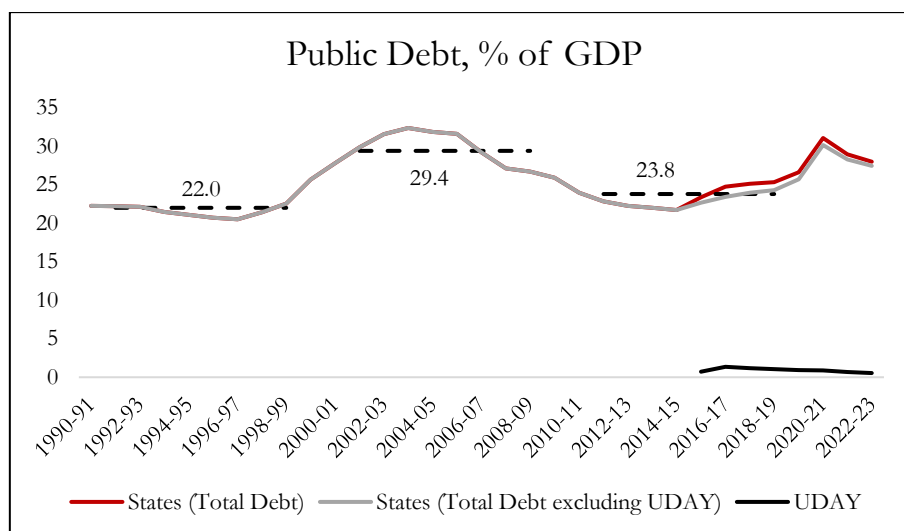

**Figure B.2: Debt Owed to the Central Government by the States and Net Public Debt of the Central Government**

Source: State Finances Report, RBI (States). For 2021-22 we have used the Revised Estimates and for 2022-23 the Budget Estimates for State's Total Debt. The chart in the left of the panel shows the total outstanding liabilities of states as % of GDP as well as the component for loans and advances from Centre as % of GDP. The chart in the right of the panel shows the states total debt and the central government net debt calculated as the difference between general government total debt and states total debt. Horizontal dashed lines are the respective decadal averages.

**Figure B.3: Share of Centre (Net Debt) and States (Total Debt) in Total Public Debt**

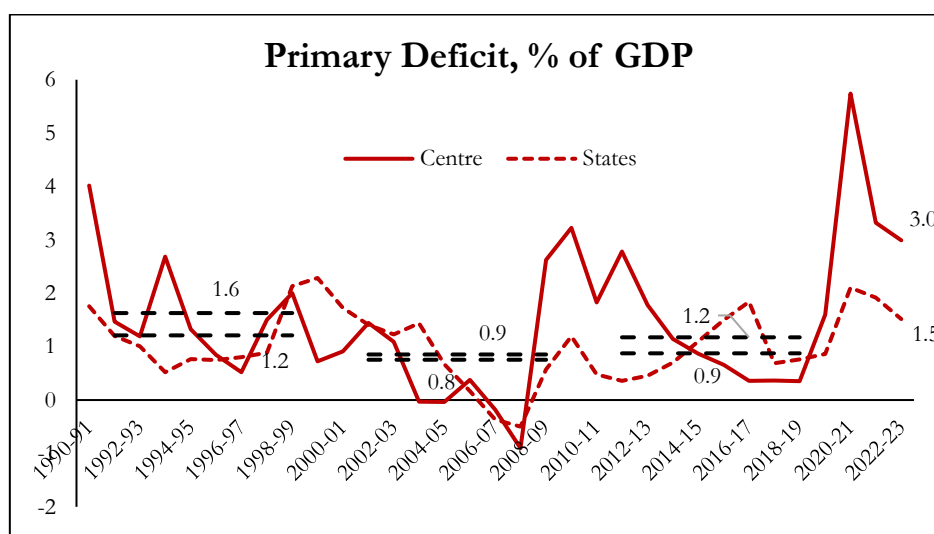

*Source:* State Finances Report, RBI (States). Net public debt for the Centre has been calculated as the difference between general government total outstanding liabilities and state's total outstanding liabilities. For 2021-22 we have used the Revised Estimates and for 2022-23 the Budget Estimates for State's Total Debt. In this chart, we are showing the share of Centre's debt and State's debt in the total general government debt (following the specification in Figure B2)

**Figure B.4: Total Debt of States and Total Debt excluding Debt on account of UDAY**

*Source:* State Finances Report, RBI (States) and CEIC (compiled from Clearing Corporation of India for Ujjwal DISCOM Assurance Yojana, UDAY). For 2021-22 we have used the Revised Estimates and for 2022-23 the Budget Estimates. The chart shows the total outstanding liabilities of State Government as % of GDP, total outstanding liabilities of States excluding UDAY as % of GDP, and debt incurred on account of UDAY as % of GDP. Under the UDAY scheme, State Governments assumed contingent liabilities on account of the loss-making electricity distribution companies (governments issued bonds in lieu of the debt owed by these companies to the banks).

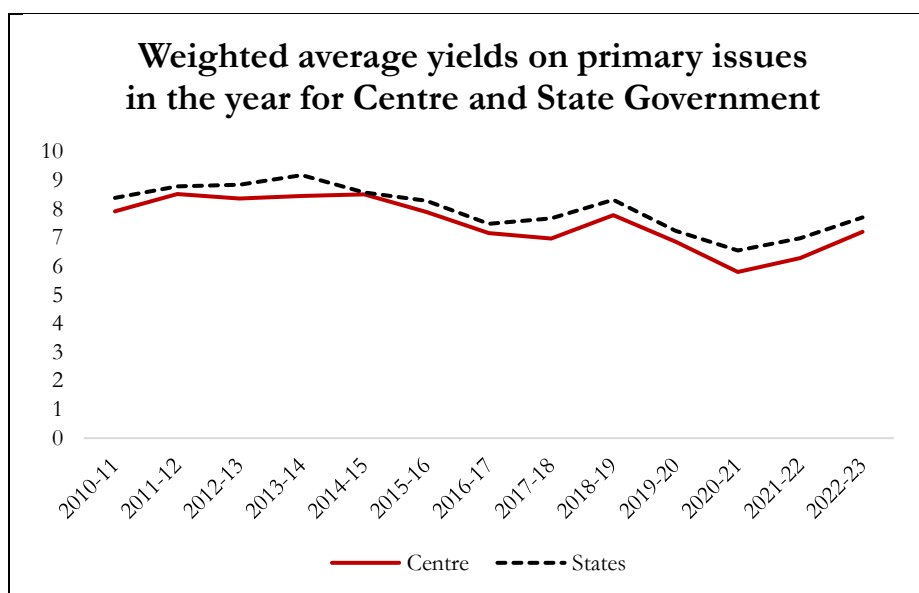

**Figure B.5: Deficit of Center and States**

*Source:* Handbook of Statistics on Indian Economy, RBI (Centre) and State Finances Report, RBI (States). For Centre, data for 2021-22 is Actual and 2022-23 is a Revised Estimate from CEIC. For States, data for 2021-22 is a Revised Estimate and for 2022-23 is a Budget Estimate. The chart shows the fiscal deficit as % of GDP for both Centre and State governments. Horizontal dashed lines are the respective decadal averages.

**Figure B.6: Primary Deficit of Centre and States**

*Source:* Handbook of Statistics on Indian Economy, RBI (Centre) and State Finances Report, RBI (States). For Centre, data for 2021-22 is Actual and 2022-23 is a Revised Estimate from CEIC. For States, data for 2021-22 is a Revised Estimate and for 2022-23 is a Budget Estimate. The chart shows the primary deficit as % of GDP for both Centre and State government. Horizontal dashed lines are the respective decadal averages.

**Figure B.7: Interest rate Paid by Centre and State governments**

*Source:* RBI (Centre and States), CEIC (individual state governments). Yields refer to weighted average yields on new issues of securities during the year.

## Appendix C: Debt-to-GDP Ratio and Interest Rates on Government Debt (General Government)

We regress nominal interest rates on debt-to-GDP ratio of the General Government, for the entire period 1990-91 to 2022-23, and different subperiods. Interest rates have been calculated as weighted average yields on Centre and State government securities using the shares of Centre and States debt in total debt as weights.

Results indicate that the interest rates do not react positively to the level of debt (Table C1). In other words, the government does not pay a premium to raise debt when its debt levels are already high. One would have expected this to be perhaps more true in the earlier years, when financial repression through high SLR and CRR, and even through the automatic monetization of deficit by the RBI was much higher. But it also remains the case for the period starting in 2010-11.

As we show in the next appendix, over time the financial repression (at least through commercial banks) has declined, and the investor base has become more diversified. Yet the non-relationship (or the reverse relationship) between interest rates and debt levels has persisted.<sup>28</sup> This could be attributed to three factors: (i) There are adequate savings and lack of alternative safe assets. (ii) Financial repression has continued but has just shifted from commercial banks to other investors, notably insurance companies and provident funds. (iii) The RBI, with a strong balance sheet (along with other large players in the market, such as the State Bank of India), ensures that yields remain low.

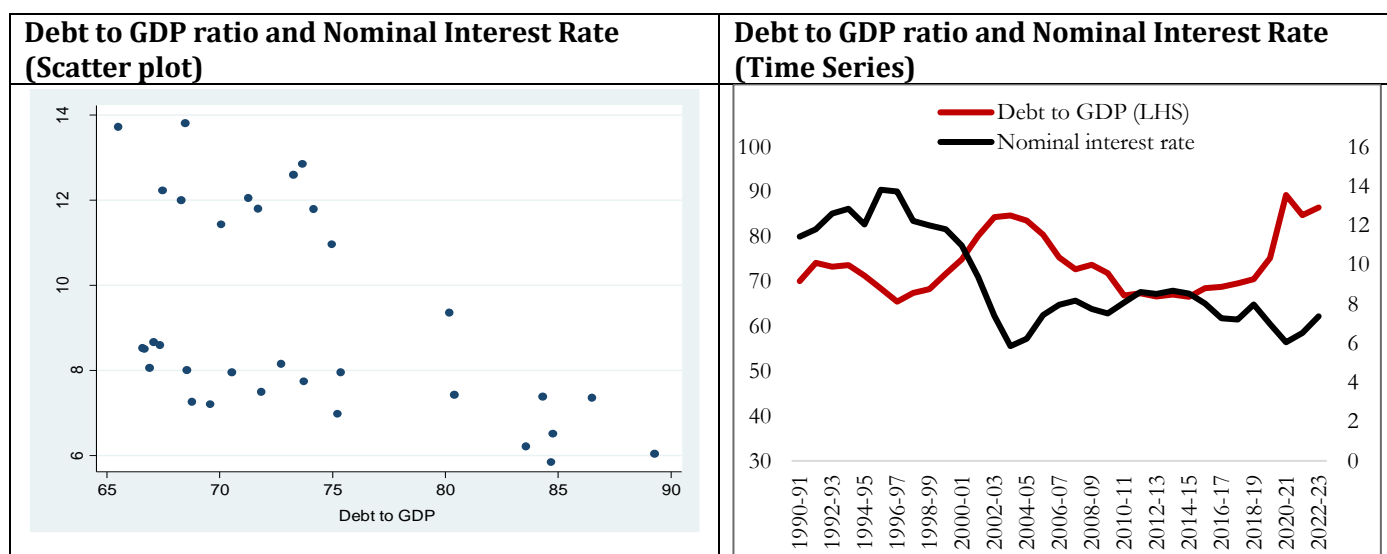

We repeat the exercise with real interest rates, and find that the real interest rates do not react positively to the level of debt (Table C2).

**Table C1: Results from Regressing Nominal Interest Rate on Debt- to-GDP Ratio of the General Government**

	(1) Nominal interest rate (yields)	(2) Nominal interest rate (yields)	(3) Nominal Interest rate (yields)
Debt to GDP ratio	-0.18*** (3.23)	-0.08** (2.77)	-0.08*** (4.71)
Constant	22.42*** (5.44)	13.65*** (6.37)	13.72*** (10.62)
No. of Observations	33	23	13
Years included	1990-91 to 2022-23	2000-01 to 2022-23	2010-11 to 2022-23

*Note:* t statistics in parentheses. \*, \*\*, \*\*\* refer to significance at 10, 5, and 1 percent levels, respectively. Nominal interest rate for general government has been calculated as the weighted average yield on Centre and State government securities (using the shares of Centre and States debt in total debt as weights).

<sup>28</sup> Lack of positive relationship prevails when we do a similar exercise separately for Central and State governments.

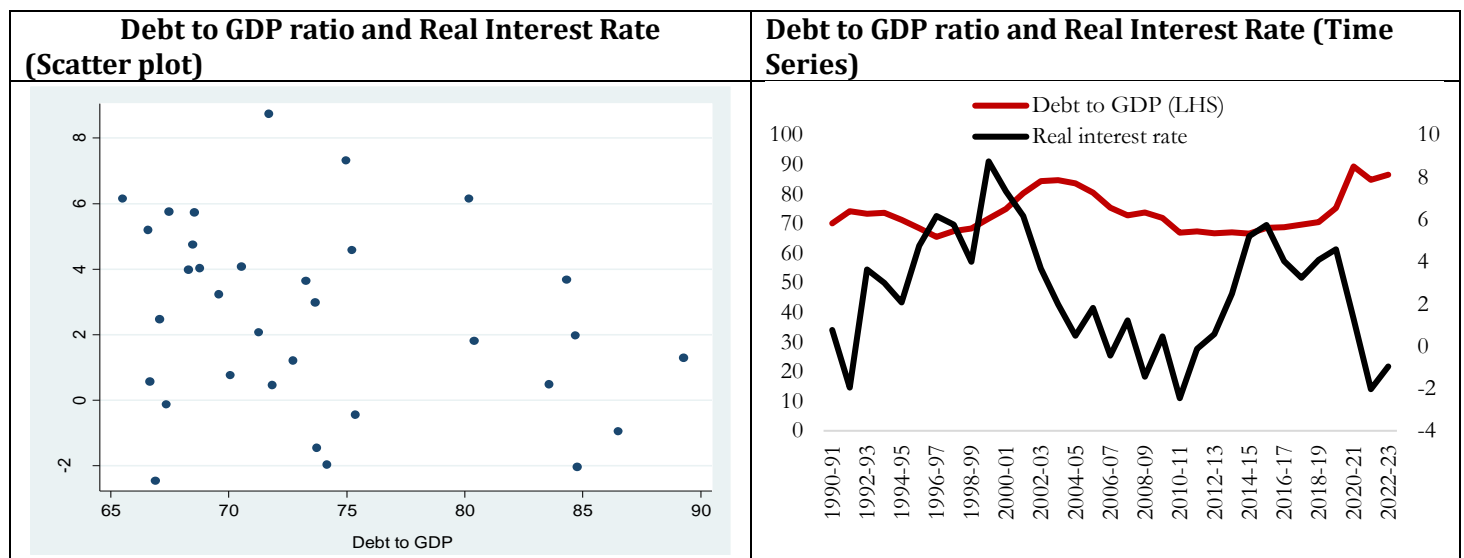

**Figure C 1: Co-movement of Debt-to-GDP Ratio and Nominal Interest Rate**

Source: CEIC (General government debt to GDP ratio). Nominal interest rate for general government has been calculated as the weighted average yield on Centre and State government securities (using the shares of Centre and States debt in total debt as weights).

**Table C2: Results from Regressing Real Interest Rate on Debt- to-GDP Ratio of the General Government**

	(1) Real interest rate	(2) Real interest rate	(3) Real Interest rate
Debt to GDP ratio	-0.11 (1.52)	-0.06 (0.72)	-0.12 (1.32)
Constant	10.80* (1.98)	6.31 (1.05)	10.96 (1.60)
No. of Observations	33	23	13
Years included	1990-91 to 2022-23	2000-01 to 2022-23	2010-11 to 2022-23

Note: Data are from 1990-1991 to 2022-2023. t statistics in parentheses. \*, \*\*, \*\*\* refer to significance at 10, 5, and 1 percent levels, respectively. Real interest rate has been calculated as the difference between nominal interest rate and growth rate of GDP deflator (inflation rate).

**Figure C2: Co-movement of Debt-to-GDP Ratio and Real Interest Rate**

Source: CEIC (General government debt to GDP ratio). Nominal interest rate for general government has been calculated as the weighted average yield on Centre and State government securities (using the shares of Centre and States debt in total debt as weights).

## Appendix D: Bank-Sovereign Nexus

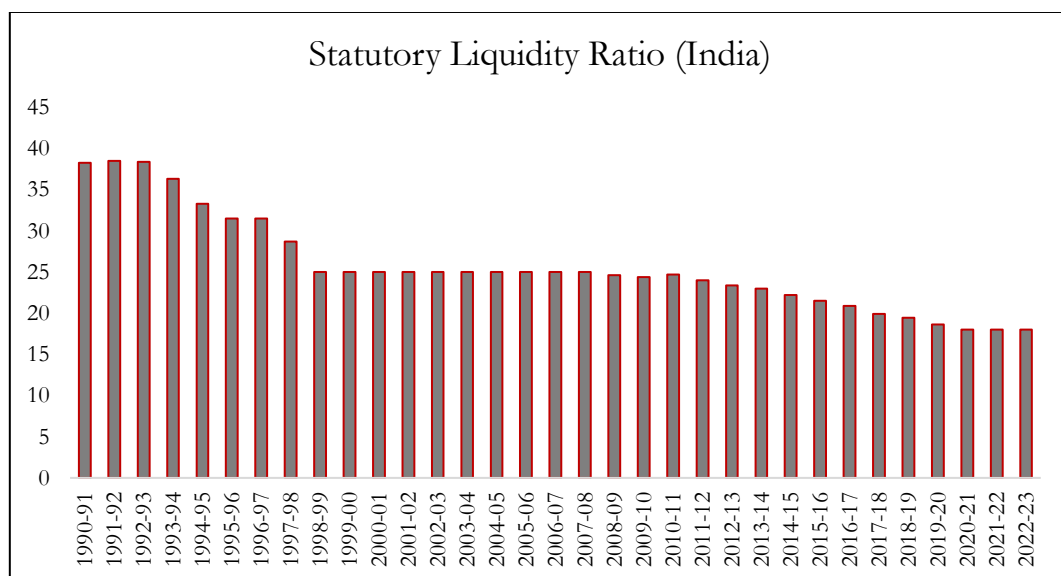

The following five kind of investors hold government securities: banks, insurance companies, provident funds, the RBI, and a residual category, which includes retail investors, cooperative banks, and mutual funds, among others. Their relative shares have changed in the last decade, over which the share of banks has declined, whereas those of the other four investors have increased (Figure D2).

The government owns a large part of each segment. For instance, it owns 12 banks (21 banks are private) and 7 of the largest insurance companies (50 insurance companies are private). Government banks accounted for 60 percent of total bank assets), while government insurance companies accounted for about 80 percent of the industry's total assets (as of 2020-21).

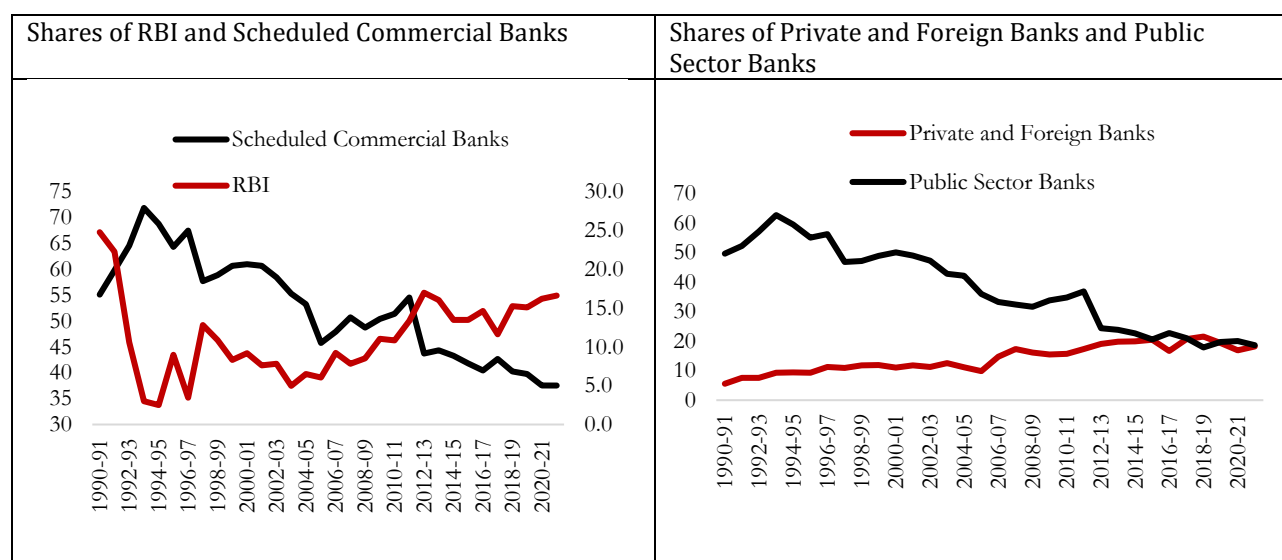

Banks, insurance companies, and provident funds have statutory requirements to invest in government securities (for the banks, for example, see Figure D1). But public banks have traditionally held more than the mandated share of their assets in government securities (Gupta, Kochhar and Panth, 2015). Their SLR ratio has declined from about 40 percent in the early 1990s to 18 percent currently, while public sector banks have reduced their excessive shares in these securities. They now hold only a slightly larger share of their assets in government securities compared to private banks.

Both insurance companies and provident funds face statutory requirements to invest about 50 percent of their respective investable funds in government securities. In recent years, the provident fund has requested the government to allow it to increase the share of its investments in government securities, from 50 percent to 65 percent in 2016, and again to 75 percent in 2022. This request indicates a lack of options as far as other safe, long-term, and liquid assets are concerned (the corporate bond market is thin, and its secondary market has very little volume and liquidity).

**Figure D1: Statutory Liquidity Ratio**

Source: CEIC (Compiled from Reserve Bank of India). Daily SLR has been averaged during the fiscal year to get annual average SLR for the respective fiscal years.

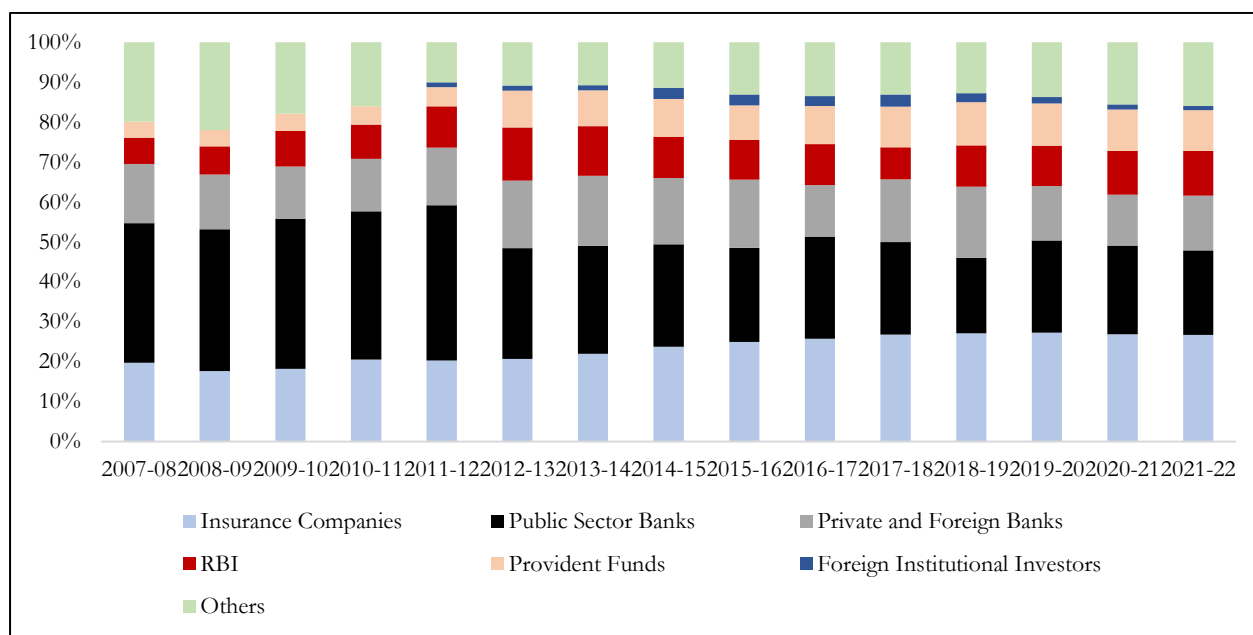

**Figure D2: Share of Public Sector Banks, Private Banks and the RBI in Central Government Securities**

Source: Handbook of Statistics on Indian Economy, RBI.

**Table D1: Shares of Institutions in Holdings of Central Government Securities**

	Insurance Companies	Public Sector Banks	Private and Foreign Banks	RBI	Provident Funds	Foreign Institutional Investors	Others

**Figure D4: Concentration of Ownership in Central Government and General Government Securities**

*Source:* Author's calculations. The index is calculated by adding the squared shares of RBI, Scheduled Commercial Banks, Provident Funds, Insurance Companies, Foreign Portfolio Investors, and Others (which include Mutual Funds, Co-operative Banks, Primary Dealers, Financial Institutions, Corporates, and State Governments) in total Central Government or General Government securities.
