ESTIMATION OF SAM FOR INDIA: AN APPLICATION FOR INDIA'S ENERGY TRANSITION TARGETS

NCAER Working Paper

Chetana Chaudhuri¹, Devender Pratap² and Sanjib Pohit³ (NCAER)

Abstract

The Social Accounting Matrix (SAM) for India was historically constructed based on Input-Output table (IO). But from 2011-12, Government of India, is publishing Supply-Use table, instead of input-output table. While erstwhile Input-Output Table published by Government of India had same number of products and industries, Supply-Use table provides one 'Supply matrix' and one 'Use matrix', each of which is a rectangular table with 140 products and 66 industries (for 2018-19). Converting the Supply-Use table to a square Input-Output table and subsequently extending it to Social Accounting Matrix require utilisation of various data sources, application of numerous steps and adjustments, and there are not many literatures on it, despite the usefulness of both IO and SAM matrices in macroeconomic policy design. This study aims to bridge the gap by constructing Input-Output Table and Social Accounting Matrix for India from the Supply-Use table incorporating information from many other sources, and describes the method of construction of the matrices. Our IO and SAM also focus on various energy sectors, including different sources of power generation, biomass etc. and disaggregate energy-intensive sectors like cement or aluminium, considering the immense usefulness of the energy-extended macro structure to research of energy and environment policies. The study focuses on construction of a 59×59 SAM for India, with base year of 2021-22 incorporating 3 factors of production and 10 categories of households. As an application of the newly constructed SAM, we have analysed the employment implication of India's Nationally Determined Contribution (NDC) emission commitments.

1. Introduction

A Social Accounting Matrix (SAM) depicts the entire circular flow of income for an economy in a square matrix format. It shows production leading to the generation of incomes which, in turn, are allocated to institutional sectors. These incomes are either spent on products or saved. The expenditures by institutions lead to production by domestic industries as well as supply from rest of world. Hence, a SAM can be used to analyse the relationship between production structure, income distribution and consumption profile of different household groups in an economy. Unlike a closed input-output (IO) model that uses a single household sector, a SAM typically models households by various occupation/expenditure classes. The literature suggests that an inter-industry analysis can be seriously misleading without incorporating these aspects (Roland-Holst 1990).

An important application of SAM is multiplier analysis. A multiplier analysis enables one to understand the direct, indirect and induced impacts of an exogenous demand shock on the economy. The direct effect is caused by the expansion of production of other activity sectors that need intermediate inputs of the manufacturing process. For example, agricultural production requires inputs of other activities and this demand, in turn, affects production of its inputs. The indirect effects occur due to the relationships between consumption and intermediate demand among the activity sectors. To satisfy the input requirements of the agricultural sector, remaining activities require other inputs and this generates additional production effects. The induced effects occur due to the circular flow of income. The production of each activity generates a feedback process from the incomes of the production factors to the expenditures of the institutional sector and to each activity's own productive process.

A SAM can be used as the database of Computable General Equilibrium (CGE) Models, which are widely used to analyse the aggregate welfare and distributional impacts of policies across various areas like fiscal reform and development planning, international trade, structural adjustment programmes, impact assessment studies, environmental regulations etc. For the above reasons, the construction of SAM has been undertaken by researchers in numerous countries over the past decades. India is not an exception to this work. India was an early leader in the construction of Social Accounting Matrix (SAM).

However, the SAMs for India was historically constructed based on the input-output table along with other data sources. But from 2011-12, Government of India, is publishing Supply-Use table (SUT), instead of the Input-Output table. The two types of tables, though both talk about the structure of Indian economy, are different in structure. While Input-Output Table had same number of products and industries, Supply-Use table provides one 'Supply matrix' and one 'Use matrix', each of which is a rectangular table with 140 products and 66 industries¹. Converting the Supply-Use table to a square Input-Output table and then extending it to Social Accounting Matrix requires utilisation of various data sources, application of numerous steps and adjustments, and there are not many literatures on it. We wanted to make an updated Social Accounting Matrix which, apart from its usage in policy assessment studies, can be used as an important input to the macro models like Computable General

¹ For 2018-19.

Equilibrium. So, we required the updated SAM, which is benchmarked with macro-data of the year 2021-22. This study aims to construct a Social Accounting Matrix for India from the Supply-Use table while also incorporating information from many other sources, and describes the method of construction of the matrices. A consequent Input-Output table is also generated and presented in the paper.

The focus of our Input-Output Table and the SAM is energy sector. Hence, energy sectors are disaggregated in detail using different data sources and also energy-intensive sectors in the economy like cement or aluminium are disaggregated from their parent sectors. Biomass is also extracted out from different sectors which contribute to the output of the biomass sector. The IO matrix and SAM are thus generated and provided in this paper to the research community, considering the immense usefulness to macroeconomic and policy research, especially in the context of energy and environment policy design.

To our best knowledge, Sarkar and Subbarao (1981) constructed the first SAM for India. Subsequently a number of SAMs were constructed by the different researchers. Table 1 depicts the developments since 2000 decade on a national level². Majority of the papers constructing SAM (after 2000) is based on Input-Output Table (Pradhan, Saluja and Singh 2006; Saluja & Yadav 2006; Sinha, Siddiqui. and Munjal 2007; Pal, Pohit and Roy 2012; Pal and Pohit 2014; Pradhan, Saluja and Sharma 2013; Pal, Ojha, Pohit, & Roy 2015; Pal and Bandarlage 2017). Supply-Use table is utilised in Venkatesh and Pal (2018) and Pal, Pradesha and Thurlow (2020), but with different sectoral emphasis and with different data sources. Majority of the papers considers occupational status of the households as a basis of classification of households as agents (Pradhan, Saluja and Singh 2006; Sinha, Siddiqui. and Munjal 2007; Pal, Pohit and Roy 2012; Pal and Pohit 2014; Pradhan, Saluja and Sharma 2013; Pal, Ojha, Pohit, & Roy 2015). A few studies classified household based on expenditure classes (Saluja & Yadav 2006; Pal and Bandarlage 2017; Pal, Pradesha and Thurlow 2020).

² SAM has also been constructed at subnational level for a few states of India. These are not included here.

Table 1: SAMs of India, 2000 Onward

S. No.	Name of researchers and their SAM based study	Salient Features of SAM.
1.	Pradhan, Saluja and Singh (2006)	<p>Base year: 1997-98.</p> <p>Sectors (57 in all): agriculture (4), livestock products (2), forestry, mining, manufacturing (27), machinery and equipment (6), construction, electricity, transport (2), gas and water supply, other services (11).</p> <p>Agents: government, self-employed in agriculture (rural & urban), self-employment in non-agriculture (rural & urban), agricultural wage earners (rural & urban), other households (rural & urban), private corporate, and public non-departmental enterprises.</p>
2.	Saluja and Yadav (2006)	<p>2. Base year: 2003-04</p> <p>Sectors (73 in all): agriculture, allied and mining (21), manufacturing (35), construction (1), electricity, gas and water supply (3), transport (2), other services (11).</p> <p>Agents: 5 rural households' expenditure classes, 5 urban households expenditure classes, private corporation, public enterprises and government.</p>
3.	Sinha, Siddiqui, and Munjal (2007)	<p>Base year: 1999-2000.</p> <p>Sectors (13 in all): agriculture (informal), formal manufacturing (9), construction (informal), other services (formal & informal), and government service.</p> <p>Agents: casual labour (rural & urban), regular wage earner (rural & urban), own account worker (rural & urban), employer (rural & urban), and government.</p>
4.	Pal, Pohit, and Roy (2012)	<p>Base year: 2003-04.</p> <p>Sectors (85 in all): agriculture and allied activity (21) mining and quarrying (9), manufacturing (32), Construction (1), Electricity and water supply (5), Transport (5) and Services (12).</p> <p>Agents: non-agricultural self-employed (Rural), agricultural labour (Rural), other labour (Rural), agricultural self-employed (Rural), other households (Rural), self-employed (Urban), salaried class (Urban), casual labour (Urban), other households (Urban), Private corporate, Public non-departmental enterprises and Government.</p>
5.	Pal and Pohit (2014)	<p>Base year: 2006-07.</p> <p>Sectors (35 in all): agriculture livestock products forestry and fishing (7) mining (4), manufacturing including machinery and equipment (12), Hydroelectricity, thermal electricity, nuclear electricity, and biomass (4), water supply, construction, transports (6) and Health and Medical Service; and other services (2).</p> <p>Agents: non-agricultural self-employed (Rural), agricultural labour (Rural), other labour (Rural), agricultural self-employed (Rural), other households (Rural), self-employed (Urban), salaried class (Urban), casual labour (Urban), other households (Urban), Private corporate, Public non-departmental enterprises and Government.</p>
6.	Pradhan, Saluja, and Sharma (2013)	<p>Base year: 2007-08</p> <p>Sectors (78 in all): Agriculture, Allied Activities (22), and Mining (9), Manufacturing Industries (27), Construction (1), Electricity, and Water Supply (2), Transport (5), Other Sectors (12)</p>

		Agents: Non-agricultural Self-Employed (Rural), Agricultural Labour (Rural), Non-agricultural Labour (Rural), Agricultural Self-Employed (Rural), Other households (Rural), Self-Employed (Urban), Salaried Class (Urban), Casual labour (Urban), Other households (Urban).
7.	Pal, Ojha, Pohit, and Roy (2015)	Base year: 2006-07 Sectors (35 in all): agriculture livestock products, forestry and fishing (7) mining (4), manufacturing (12), electricity (3), biomass (1), water supply, construction, transports (6) and Services (2). Agents: Non-agricultural Self-Employed (Rural), Agricultural Labour (Rural), other labours (Rural), Agricultural Self-Employed (Rural), Other households (Rural), Self-Employed (Urban), Salaried Class (Urban), Casual labour (Urban), Other households (Urban), Private corporate, Public non-departmental enterprises, Government.
8.	Pal and Bandarlage (2017)	Base year: 2007-08 Sectors (78 in all): agriculture livestock products, forestry and fishing (22) mining (9), manufacturing (26), water supply, construction, transports (7) and Services (13). Agents: 10 rural ST households' expenditure classes, 10 rural SC households' expenditure classes, 10 rural OBC households' expenditure classes, 10 rural 'Others' households' expenditure classes, 10 urban ST households' expenditure classes, 10 urban SC households' expenditure classes, 10 urban OBC households' expenditure classes, 10 urban 'Others households' expenditure classes, private corporation, public enterprises and government.
9.	Venkatesh and Pal (2018)	Base year: 2012-13 Sectors (140 in all): agriculture livestock products, forestry and fishing (29) mining (11), manufacturing (72), electricity (1), water supply, construction, transports (11) and Services (16). Agents: household consumers, industries, government, labour, capital and ROW. Institutions comprise households, private corporate sector, public non-departmental enterprises and government.
10.	Pal, Pradesha and Thurlow (2020)	Base year: 2017-18 Sectors (112 in all): agriculture and allied (39), agriculture-based processing activities (18), mining (4), manufacturing other than agro-processing (24), utilities (3), construction (1) and services including transport and trade (23). Agents: 10 expenditure classes for rural farm households, 10 expenditure classes for rural non-farm households and 10 expenditure classes for urban households.

Source: Authors' compilations.

As Table 1 shows, a major shortcoming of the SAMs of India is the aggregate treatment of energy sectors. However, the SAMs constructed by Pal, Pohit, address these shortcomings. However, the renewable energy sectors are not fully disaggregated in these SAMs. However, energy sectors need to be disaggregated if one has to undertake environmental analyses, particularly in view of net zero commitment by India. And also, as mentioned earlier, majority of the SAMs are based on Input-Output table published by Government of India, not the Supply-Use table, which Government of India is publishing since 2011-12, instead of Input-Output table. Therefore, we have constructed a new SAM.

In recent years, many literatures have utilised SAM to analyse and assess the macro-economic impacts of different policies in the context of different countries. For

example, Njoya (2023) utilised SAM for Tanzania for assessing the poverty impact of the COVID-19-induced tourism crisis in Tanzania. Hartono et al. (2020), in the context of Indonesia, analysed the impacts of fossil and renewable energy investments using SAM. Tiku et al. 2022, is also based on SAM multiplier analysis while analysing tourism-induced distribution effects on various socioeconomic groups in West Papua Province. Ferrari et al. (2022) also utilised SAM in their study on the role of tourism in China's economic system and growth. Betho et al. (2022), in their study on macroeconomic impact of COVID-19 in Mozambique through SAM approach has used SAM. Mardones & Brevis (2021) constructed social accounting matrix with environmental accounts for analysing energy and environmental policies in Chile. Morrissey et al. (2019), analysed the distributional impact of investment in the port sector on households in Mauritius through Social Accounting Matrix approach. SAM is considered a very important policy tool for analysing the impact of different policies in macro-economic context, but there is no SAM for India published after 2021, to the best of author's knowledge. The year 2021-22 is chosen as the base-year, also, because that was the 'normal' year after COVID-19. Major contribution of the paper is construction of India's SAM from SUT, which, despite being worked on in some institutes, is not also published in any major journal. One of the major contributions of the paper is that in this paper while preparing SAM from SUT, the conversion of purchaser's prices to basic prices was done after adjusting the Trade and Transport margin and Net Product Tax including Tariff Matrix, following the standard rule used by UN (UN 2018).

The plan of the rest of the paper is as follows. Section 2 discusses materials and methods, which talks about Supply-Use matrix and its link with Social Accounting Matrix, construction procedure of our Input-Output table followed by construction methodology of overall SAM, Section 3 describes the results, with sub-sections on structure of the Indian economy, factor and energy demand analysis using SAM multipliers, employment implication of India's environmental policy target. Finally, section 4 summarises our findings and provides concluding remarks. The Input-Output table and the Social Accounting Matrix are presented in Appendix II & III in the paper, respectively, provided in the Supplementary file.

2. Material and Methods

The methodology of construction of SAM consists of a number of steps, which broadly can be classified as: construction of Input-output table from Supply-Use Table, expansion of energy sector into 7 categories based on the source of generation, bifurcation of biomass from several sectors, and construction of sectors other than production account in SAM. Our study uses the available dataset for India in best way possible with the benchmark of the macro-economic variables, and the step-by-step method is explained in the paper, which can be utilised in the context of other countries as well.

2.1. Supply Use Table and Social Accounting Matrix Framework

The SUT for India³ includes the following tables: (1) Supply Table at purchasers' price, containing the information on domestic and imported supply of commodities at basic price, commodity-specific taxes and -margins; (2) Use table at purchasers' price, containing the information on use of commodities by users valued at purchasers' price; (3) The value added by industry is presented at the bottom of the Use table. SUTs describe the entire economy by industry and products. The tables show links between components of Gross Value Added (GVA), industry input and outputs and the commodity supply, and the use of these commodities. The Supply table shows where commodities are sourced from either the local market or imported from the rest of the world. The Use table shows the use of these commodities either as an intermediate input in production, used by domestic final consumption or exported to the rest of the world. The basic price is the amount receivable by the producer from the purchaser for a unit of a good or service produced as output, minus any tax payable (i.e. VAT and excise duties), and plus any subsidy receivable, on that unit as a consequence of its production or sale. Basic prices exclude any transport charges involved separately by the producer. The producers' price is the amount receivable by the producer from the purchaser for a unit of a good or service produced as output, minus VAT, or similar deductible tax, invoiced to the producer. It excludes any transport charges invoiced separately by the producer. The purchasers' price is the amount paid by the producer, excluding any deductible VAT or similar deductible tax, in order to take delivery of a unit of good and service at the time and place required by the purchaser. The purchasers' price includes any transport charges paid separately by the purchaser to take delivery at the required time and place. There are 140 commodities and services, and 66 domestic industries or imported from abroad, illustrated in the Supply and Use table in SUT 2018.

A schematic presentation of the Social Accounting Matrix (SAM) is shown in Table 2. Input-Output table corresponds to the production account, and appears in the cell A11 of the schematic SAM. There are four agents in this model economy: households, private corporate, public non-departmental enterprises and the government. Factor incomes generated through production process (A21) are transferred to institutions according to the ownership of their factors of production (A32, A42, A52, and A62). Household's income also includes current transfers from the government, interest on public debt (A36) and the net current transfers from the rest of the world (A39). The households spend on consumption of goods and services (A13), and pay direct income taxes (A63) and indirect taxes on purchase (A73) and residual income is saved (A83). Private corporate sector's income consists of operating profit (A42) and interest on public debt (A46). The income, excluding the corporate tax (A64), is its saving (A84). The income of the public-non-departmental enterprises is only the operating surplus (A52), which is same as their saving (A85). The receipts of the government include income from its enterprises (A62), direct taxes of the households and private corporations (A63, A64), the total indirect taxes of the economy (A67) and the net capital transfer from rest of the world (A69). Government spends on its final consumption expenditure on goods and services (A16), transfers and interest payments to households (A36) and interest payments to private corporate sector (A46). The receipts of the capital account comprise net savings of the different institutions (A83,

³ <https://mospi.gov.in/publication/supply-use-tables>

A84, A85 and A86), foreign savings (A89), and depreciation (A82). The Capital account expenditure is equal to gross domestic capital formation (A18) and indirect taxes paid on purchases of the investment goods (A78). The rest of the world (ROW) represents the equality between foreign exchange expenditures on one the hand and foreign exchange earnings on the other.

Since 2011-12, a new series of national accounting is published by National Accounts Division, Ministry of Statistics and Programme Implementation, Government of India, namely Supply-Use table (SUT). The SUT framework describes the production in industries in which intermediate products and primary inputs are required, and utilisation of the produced goods and services as intermediate consumption, final consumption, gross capital formation and exports. Supply Table shows the value of the products by kind of supplier. Entries across the column in a Use Table describe use of the respective product (good or service) in intermediate consumption by industries, final consumption, gross capital formation and exports. The study uses SUT for 2018-19 published by Government of India, where one 'Supply' and one 'Use' table are provided, each encompassing 140 products and 66 industries.

Given the available data, the objectives of our study, and time constraint, we have decided to construct a 59 sectors SAM for India. The base year of our SAM is 2021-22 and it incorporates 3 factors of production and 10 categories of households. Table 3 gives the description of our sectors and its concordance map with 140 products and 66 industries of SUT table of 2018-19.

Table 3: Mapping between SAM Sectors and Sectors of Supply-Use Table

Sec Code	SAM Sectors 2021-22	Product classification of SUT 2018-19	Industry classification of SUT 2018-19	Sec Code	SAM Sectors 2021-22	Product classification of SUT 2018-19	Industry classification of SUT 2018-19

Source: Authors. The description of 140 products and 66 industries in Supply and Use Table of SUT is given in Appendix I.i. and Appendix I.ii.

The important aspect of our SAM is the decomposition of the electricity sector into seven separate sectors viz. Nuclear, Solar, Wind, Hydro, Gas, Coal and Other. Energy-intensive sectors in the economy like cement or aluminium are disaggregated from their parent sectors. Biomass is also extracted out from different sectors which contribute to the output of the biomass sector.

We have considered 4 broad economic agents in our proposed SAM viz. households, government, public non-departmental enterprises, and private corporations. Moreover, households are decomposed into 10 households group based on their consumption quintiles (Table 4).

Table 4: Description of Economic Agents

Agent code	Description
RH1	Rural, 1 st quintile (lowest)
RH2	Rural, 2 nd quintile
RH3	Rural, 3 rd quintile
RH4	Rural, 4 th quintile
RH5	Rural, 5 th quintile (highest)
UH1	Urban, 1 st quintile (lowest)
UH2	Urban, 2 nd quintile
UH3	Urban, 3 rd quintile
UH4	Urban, 4 th quintile
UH5	Urban, 5 th quintile (highest)
PVT	Private corporate
PUB	Public non-departmental enterprises
GOV	Government

Source: Authors.

The underlying assumptions in a SAM model are: (1) prices and expenditure propensities of endogenous accounts are constant; (2) government, rest of the world, and capital accounts are considered to be exogenous, while the factors, institutions and sectoral production activities are endogenous; and (3) production technology and resource endowments are given for a time period (Babu et al. 2018).

2.2. Methodology for Constructing Social Accounting Matrix (SAM)

In our study, the methodology of construction of SAM is primarily based on Pradhan (2006) and Pal, Ojha, Pohit, & Roy (2015). Though these studies prepare SAM from Input-Output table, the basic methodology is similar. Our study prepares SAM from Supply-Use Table, which is an extension of the methodology incorporating the standard methodology of preparation of Input-Output Table from Supply-Use Table (UN 2018). Since, Government of India publishes Supply-Use Table instead of Input-Output Table since 2011-12, our contribution in the literature is to generate a SAM for India from Supply-Use Table. Input-Output Table is a by-product of the exercise. An attempt of developing Input-Output Table from SUT for India for the year 2013-14 has been undertaken by Singh and Saluja (2018), but our objective was to prepare SAM, which

not only provides a broader economic perspective by including income distribution of households, but also generates a basic structure for CGE modelling. So, the SAM for Indian economy is prepared with the base-year of 2021-22.

2.2.1. Construction of Input-output table from Supply-Use Table

Both the Supply Table and Use Table of India are product X industry matrices but their entries are different. In the Supply Table, each column presents the values of products (kept in rows) produced by an industry or the products supplied by industries to the economy distinguishing the domestic supply from foreign supply (imports). The supply table documents the availability of individual commodities of goods and services and usually valued at basic prices. The total supply of each product at the purchaser's price has been obtained by adding taxes less subsidies on products and trade and transport margins. On the other hand, a Use Table shows the use of the product (a good or service and kept in rows) by the type of use (kept in columns), that is, as intermediate consumption, gross capital formation, and exports. They are all at purchaser's price.

For transforming rectangular SUTs to square SUTs, we needed to follow two major steps: First, the products included in the SUTs were disaggregated or aggregated in a way so that they represent the characteristic products of industries shown in the columns; and second, the industries included in the columns of SUTs are disaggregated or aggregated in a way so that they correspond to the products shown in the rows. Following either of the step, the resultant square SUT will show in rows, the characteristic products corresponding to the industries included in the columns. The choice of either of the two options depends on the size of the IO table to be compiled from the SUTs. We should also consider that as products included in SUT are often more than the industries in the rectangular SUTs, the option of disaggregating the industries would result in a larger size IO table. Conversely, if products are aggregated to correspond to the industries, the size of IO will be smaller. In general, aggregation approach is preferred, as disaggregation requires lot more efforts in collecting detailed data, and such compilations involved would almost be equivalent to compiling the SUTs afresh. The criterion of any product, to be the characteristics product(s) of an industry or in other words, any industry to be a producer of single or more products, was based on specialisation and coverage ratios based on supply matrix. The specialisation and coverage ratios are share matrices respectively in column totals and row totals. This provides us a mapping between 140 products and 66 industries or vice versa.

The commodity x commodity IO table is constructed following the method suggested in *System of National Accounts, Studies in Method Series F. No. 2, Revision 3, 1968 (UN)* under industry technology.

That, commodity x commodity Flow table is derived as follows:

$$(BD) q = X (g)^{-1} M (q)^{-1} q = X (g)^{-1} M$$

where,

X is use matrix,

M is supply matrix,

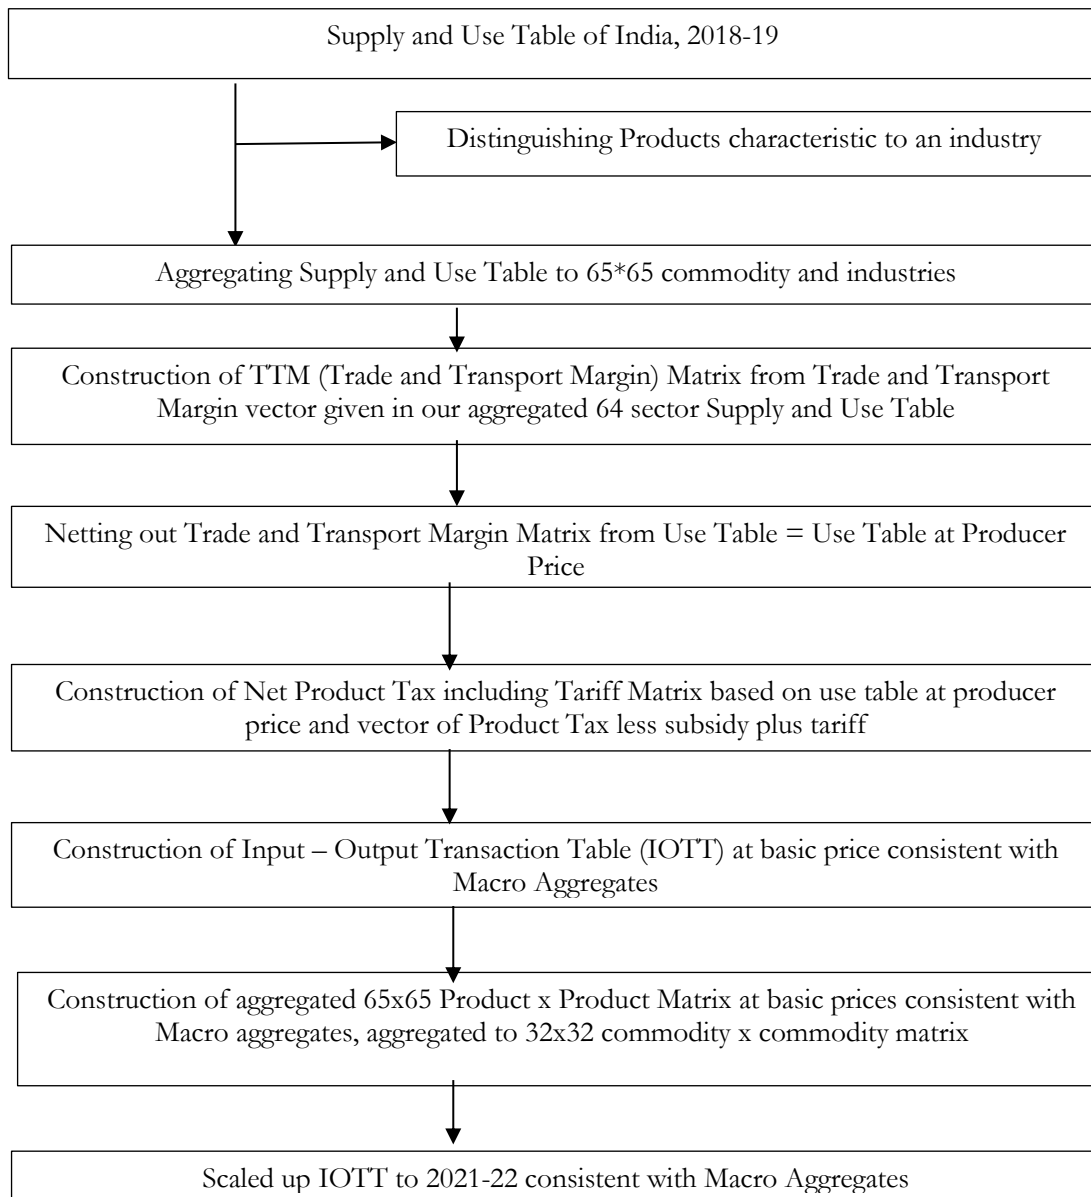

B = X (g)⁻¹: commodity x industry coefficient matrix, values in the use matrix expressed as coefficient; g is a diagonal matrix with diagonal elements as the elements of vector g; (g)⁻¹ is the inverse of the matrix g

$D = M (q)^{-1}$: where q = diagonal matrix with diagonal elements as the elements of vector q ; $(q)^{-1}$ is the inverse of the matrix q .

Here, D is basically the Market share matrix, the column of which show proportions in which various industries produce the total output of a particular commodity.

The flowchart of the construction procedure of our SAM begins with the construction of an IO Table from the published SUT of India as shown in Figure 1. As Figure 1 indicates, initially, after aggregation, we have with us one aggregated supply table and one aggregated use table, each with 65x65 dimension. For balancing the two tables and finally bringing them to an analysis, it is essential that both the tables are brought to the same valuation prices using Trade and Transport Margin Matrix and Net Product Tax including Tariff Matrix. The detailed procedure is shown in Figure 1. Here, we want to mention that the sectors like aluminium and cement are not shown as separate sectors/ industries in SUT tables. These have been separated out from their parent sector by drawing on their structure from detailed ASI statistics. Most of these products originate in the registered sector, which are covered in the ASI statistics. We have not made any adjustment in their contribution originating in the unorganised sector. The 32-sector uniform IO table is scaled up to the year 2021-22 using latest national account statistics. The consistency of IO table hence prepared for 2021-22 is further checked for both income and expenditure side.

Figure 1: Flow Chart of the Construction Procedure of Input-Output table

It may be noted that India's SUT table provides only a column "Trade and Transport margin (TTM)" that covers the trade margins and the transport cost of goods, or freight cost, from place of seller to purchaser. For all agriculture and manufactured products, TTM value is a combination of trade and transport margins. For services, TTM value is zero as it involves neither trade nor transport margin. For transport services, TTM depicts transport margins or the freight cost only.

The transport services for which these freight costs are available are: Railway Transport, Road Transport, Water Transport, Air Transport and Supporting and auxiliary transport activities.

The values of TTM for all above items present the values of freight cost for each type of transport as well as the cost of support services for each of the transport services. The support services include services such as switching and shunting (in the case of railways), parking charges (in the case of land transport), fire-fighting services (in the case of air transport), cargo handling in all types of transport services, service charges of travel agents, etc.

The column vector of trade and margin is used to construct the matrix by distributing the column entry using output as control total in the following way:

Let us denote entry in Supply table at basic price (S) by s_{ij} , entry in Use table at purchaser price (U) by u_{ij} , entry in Use table at producer price (U_p) by up_{ij} and Trade and Transport Matrix (TTM) by ttm_{ij} . Then TTM matrix is derived as follows

$$ttm_{ij} = (S_i \text{ trade and transport margin column entry}) (u_{ij}) / (u_i \text{ total use column entry} - u_i \text{ CIS column entry})$$

The sum total of the column value is further apportioned using a share of individual margin commodity vis-a-vis row sum of all the margin commodities together. The cell entries for margin sectors in TTMs are placed as negative values. We netted out TTM matrix from use table and further arrived at use table at producer prices. For clarity, the derivation of use table at producer prices (U_p) is mentioned below.

$$up_{ij} = u_{ij} - ttm_{ij}$$

Similarly, we have constructed matrix for net product tax including tariffs by similarly allocating net product tax including tariffs column. We have taken out net product tax matrix from use table at producer prices, which further resulted into use table by product and industry dimensions.

Let NPT, be the matrix for net product tax including tariff. The derivation is as follows.

$$npt_{ij} = (S_i \text{ product tax less subsidies column entry} + S_i \text{ import duty column entry}) * \left(\frac{up_{ij}}{up_i \text{ total use column entry}} \right)$$

The use table at producer prices (U_p) and NPT are then used to construct IO transaction table at basic prices by deducing taxes from U_p table.

If we define the entry in Use table at basic price (U_b) by ub_{ij} , then

$$ub_{ij} = up_{ij} - npt_{ij}$$

2.2.2. Expansion of Energy Sector

Having constructed the 32x32 balanced IO table, we have extended the same to match with our desired sectoral scheme, and finally a matrix with 39 production sectors is generated. The procedure is outlined in the following self-explanatory charts (see Figures 2, and 3). The methodology primarily follows Pal et al. (2012), but the energy sector is expanded to generate disaggregated distribution of renewable and non-renewable energy sources of power generation.

Electricity sector is expanded into 7 sectors, namely electricity from coal (ELC), electricity from gas (ELG), electricity from nuclear (ELN), hydro-electricity (ELH), electricity from solar (ELS), electricity from wind (ELW), electricity from other sources (ELO) (Figure 2). For this, Annual Reports of HPCL NPCL, NTPC & of firms engaged in gas-based power, solar/wind electricity are utilised. Gross output of various sources of electricity are estimated using the share of generation a particular source and total output of electricity in our IO table. For example, output from electricity generation from hydro sources are estimated by multiplying the output from total electricity generation with share of hydro in total generation of electricity. For construction of columns in the SAM, Gross Value Added (GVA) values from the Annual Reports are utilised. GVA of the 'other' sector is estimated by subtracting GVA from electricity produced by coal, gas, nuclear, hydro, solar and wind from the total GVA from electricity. Similarly, for intermediate use, data from the same annual reports are utilised, and the estimates for the 'other' sector is derived by similar subtraction. Net indirect tax in total output of electricity sector is distributed among sources based on their outputs' shares in total. The shares of each of the seven electricity types are applied to total electricity rows to estimate the supply of seven different sources. Because there are some issues like there is no electricity imports except in hydro sector, few of the columns are adjusted pro rata.

Figure 2: Extension of Electricity Sector into ELC, ELG, ELN, ELH, ELS, ELW, ELO Sector

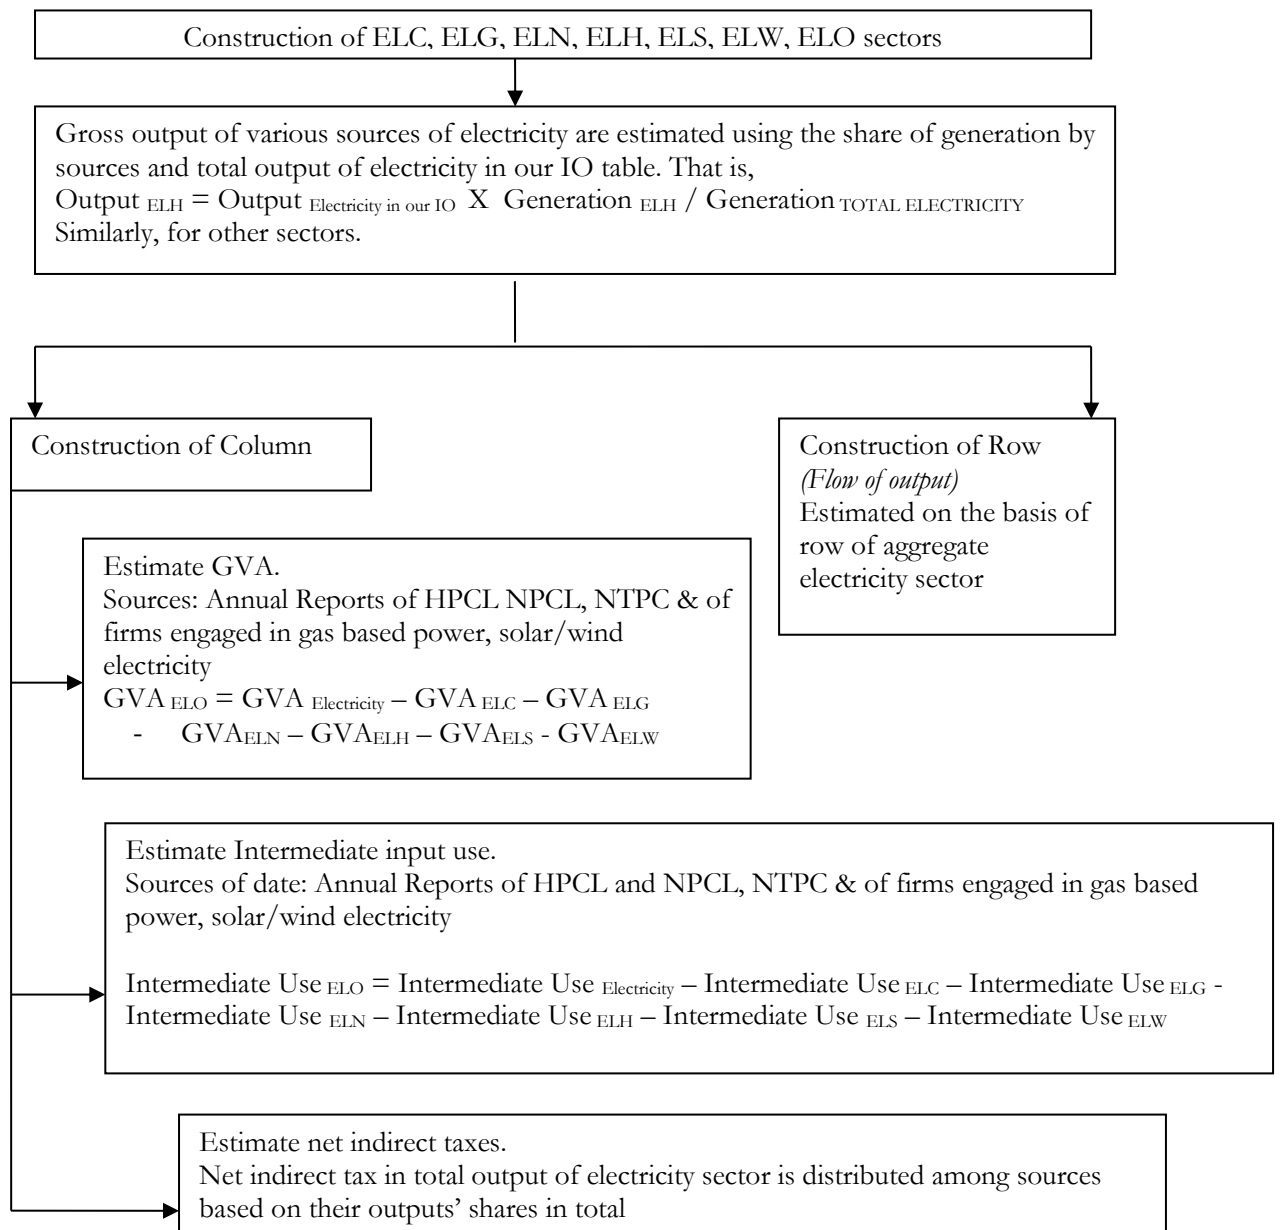

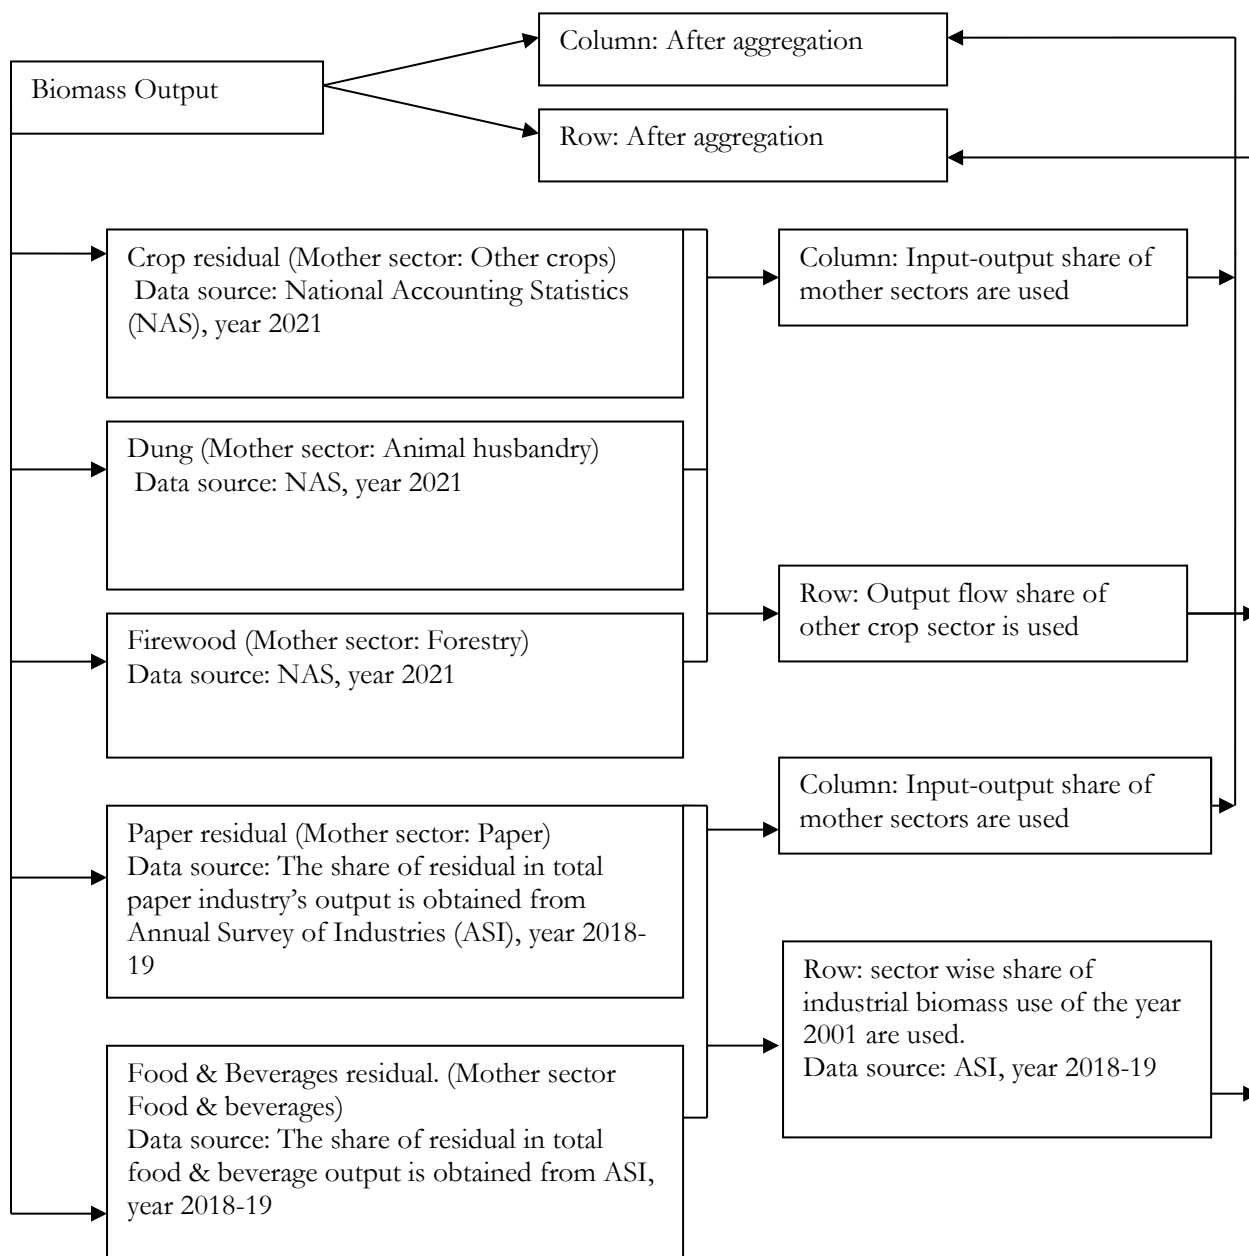

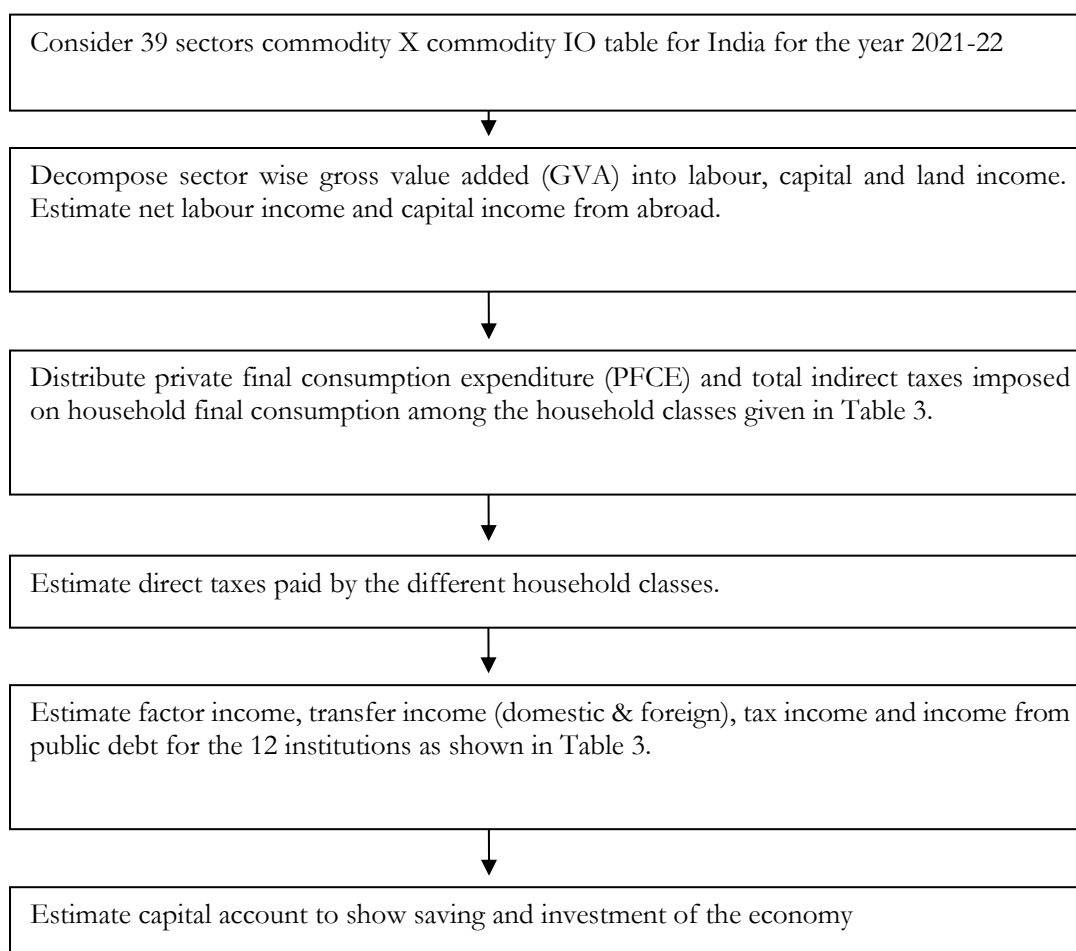

Figure 3: Extension of Sector Commodity-by-commodity IO Table with Biomass

2.2.3. Construction of Sectors other than Production Account in SAM

Apart from information from IO table, SAM requires information for Factors of Production, Households, Private Corporate, Public Non-Departmental enterprises, Government, Indirect Taxes, Capital Account and Rest of the World (ROW). The method that was applied in estimating these sectors in SAM follows the estimation process applied by Pradhan et al (2006). The flowchart in Figure 4 shows the additional path adopted by us for construction these other sectors of the SAM apart from the IO table. In the subsequent sections, we have discussed each step in the flowchart in detail.

Figure 4: Construction Procedure of SAM

2.2.4. *Division of GVA into Land, Wage and Capital Income*

The Use Table in SUT shows the components of gross value added (GVA) by industry. The components are net production taxes, compensation of employees and gross operating surplus/mixed income. For the sectors that are expanded, we split the value added for the initial industry into the new industries by multiplying the initial value added with the share.

The extension exercise of IO to SAM involves additional data which are mainly drawn from NAS of government of India, RBI's KLEM database and GTAP database. The original data provided to GTAP that was later utilised to prepare GTAP data version 11 is used in this study. In doing so, we have used the following 3 identities:

$$\text{Gross Value Added (GVA)} = \text{Net Value Added (NVA)} + \text{Depreciation} \quad (1)$$

$$\text{NVA} = \text{Payment for wage} + \text{Payment for land} + \text{Net payment for capital other than land} \quad (2)$$

$$\begin{aligned} \text{Net payment for capital excluding land} = \\ \text{Gross payment for capital excluding land} - \text{Depreciation} \quad (3) \end{aligned}$$

We have decomposed GVA into payment for wage, payment for land (if applicable) and the payment for capital (other than land). The following procedure has been used apart from the above identities:

- ASI gives the estimates of total emoluments and GVA from the registered sector for the manufacturing sector. In case of unregistered sector, we could not get similar data. The ratios of registered sector are used for unregistered sector also to get the wage and capital income.
- For agricultural sectors, we have used information from Cost of Cultivation of Principal Crops studies (CCS) of Ministry of Statistics and Programme Implementation (MOSPI) to divide the GVA into land, wage and capital income for agriculture related sectors. CCS give the data of the wages to the hired labour as well as cost of the family labour. The wage estimates given in the SAM are, therefore, inclusive of the wages of the family labour.
- For service sector, we have mainly used KLEM database and NAS statistics to decompose value added into labour and capital income.
- For electricity sectors, we have depended on annual reports of NPCL, HPCL, NTPC, selected firms engaged in solar, wind, and gas-based power station to decomposed value added into labour and capital component.).

2.2.5. Distribution of Sector-wise Consumption Expenditure by Household Classes

The updated IO table provides commodity-wise private final consumption expenditure (PFCE) for 39 sectors only. Therefore, we have to decompose PFCE for these 39 sectors into 10 household classes. The latest round of NSSO survey on consumption expenditure provides distribution of per-capita consumption expenditure for 10 household classes for a more detailed level of classification of commodities for the year 2011-12. Census also gives the distribution of the rural (urban) population for the year of our SAM. These two figures are used to derive consumption expenditure for our household class after (1) adjustment for sector-wise inflation, (2) population growth of rural and urban households.

2.2.6. Distribution of Household Income by Source of Income and by Wage and other Components

We need to estimate total personal incomes of each of our 10 household classes. The households receive income from different sources like labour income, income from capital owned by households, land income, and transfer income from government and rest of the world (ROW). In the first part of this section we have estimated payment for wage for each of the domestic sectors of our SAM. On the other hand, the net wage income from ROW is available from NAS. We have added up these wages payments to obtain households total labour income. Now, we have to distribute this labour income among the 10 household classes. This has been done using (a) information from national household surveys and (b) SAM for the year 2017-18 constructed by Pal, Pradesha and Thurlow (2020).

To estimate household income from capital ownership we have use our estimated data on payments of the domestic production sectors for the capital use. The

payment for capital along with net capital income from ROW is treated as gross capital income of the economy where the data on net capital income from ROW is available from NAS. We subtract depreciation from gross capital income to obtain net capital income of the economy. This net capital income is received by household classes as well as by economic agents like private corporate sector, public non-departmental enterprises, and government. The private corporate sector receives capital income in the form of operating profits while the public non-departmental enterprises receives the same in the form of operating surplus and the government receives capital income in the form of entrepreneurship income. The data on operating surplus, operating profit and income from entrepreneurship are available from NAS for the year 2021-22. So, the remaining part of the capital income is capital income of the households. We have distributed this capital income among the household classes by using the share of each household's capital income as available from SAM of Pal, Pradesha and Thurlow (2020).

Next, we have to estimate land income received by the household classes. The point to be noted is that only rural agricultural self-employed household class receives income from land. In this case, we have taken total payment for land factor as the total land income of that class.

The other sources of household incomes are transfer income from government and net current transfer from ROW. The NAS gives data on current transfer from government and net current transfer from ROW. The government transfer includes direct government transfer to the households and interest payment for debt. A part of this interest payment goes to the private corporate sectors due to their holding of public shares, bonds etc. We have estimated interest income received by the private corporate sector using data from NAS. Now, the remaining part of government transfer is distributed among the household classes using the information drawn from national surveys.

Thus, we have obtained households' personal income from different sources. The household personal income obtained in the above way did not match with the column total of each of the household classes of our SAM. A pro-rata adjustment has been made to obtain the control total i.e. row total of each household classes in our SAM.

2.2.7. Construction of Tax Account (Direct and Indirect taxes)

The indirect taxes reported in our SAM are net of subsidies (net indirect taxes). The net indirect taxes on household consumption and government consumption include sale taxes, excise on domestic production, and custom duties on imported goods. The decomposition of net indirect taxes across production sectors is done using the IO flow table.

The total direct taxes drawn from NAS are distributed among different categories of households in the following manner. Land revenue is paid by self-employed agricultural households. The other direct taxes are distributed among different categories of households in proportion to their personal income, assuming no direct tax to be paid by agricultural and non-agricultural labour households and self-employed rural agricultural households.

2.2.8. Construction of Capital Account

This account represents the macro balancing of savings and investments. Net savings include those by the households, the private corporate sector, the public non-departmental enterprises, the government and ROW. Net savings along with the depreciation equal gross domestic capital formation. The savings of different categories of households are derived by subtracting their consumption and direct taxes from their total personal income.

The retained earnings of the private corporate sector and non-departmental public enterprises are treated as their savings. The difference between the revenue and current expenditure of the government is its saving. The foreign savings is equal to the difference between gross domestic capital formation and gross domestic saving.

2.2.9. Treatment of Foreign Trade, Private Corporate and Public Enterprises

The column of ROW describes the exports of goods and services, net factor income from abroad, net capital transfer to the government, other current transfer to the households and private corporate and foreign savings. The data on exports are directly available from IO flow Table 2021-22. The other data are drawn from NAS and Reserve Bank of India (RBI). We put these data under the column of ROW in such a manner that the column total of ROW must be equal to the total imports.

In our study, government, capital account and Rest of the World (RoW) is treated as an exogenous sector. There are many studies where rest of the world, government and capital accounts are considered as exogenous sector. For example, Njoya (2023) mentioned that exogenous accounts comprise the rest of the world, government and capital accounts. Tiku et al. 2022 considers five exogenous accounts including government, capital balance, indirect tax minus subsidy, rest of Indonesia, and rest of the world. Ferrari et al. (2022) selected public and private expenditure, capital accounts, and Rest of the World (RoW) as exogenous account. Betho et al. (2022) defines exogenous final demand by households, government, investors and exports demand. Mardones & Brevis (2021) stated that exogenous accounts are commonly related to government spending, investment, and/or exports. Morrissey et al. (2019) aggregated Savings and investment and Rest of the World account into a single exogenous account. Hartonoa & Resosudarmo (2008) also considers 'Other' as exogenous account, which consists of corporate, government, capital account, indirect tax, subsidies and foreign transaction accounts. In the method described above, we have constructed a SAM for India for the year 2021-22 (see Appendix III in Supplementary file). This SAM consists of 39 producing sectors, 3 factors of production, and 4 economic institutions including household sector. The households are also classified into 10 broad categories according to their income quintile class in rural and urban area in this SAM. Having filled up the entries in this way, RAS technique is applied so that row total of each row matches the corresponding column total of each column. In this way, consistent SAM of India is estimated.

2.2.10. Estimation of SAM Multiplier

Given this structure of the Indian economy, let us now discuss the impact on factor demand and energy use due to any exogenous change in the Indian economy. This is done using the methodology of SAM multiplier analysis.

Let A be the domestic expenditure coefficient matrix and X be the matrix of sector-wise gross output. Also, let Y_{exo} be the exogenous account comprising government, capital account and Rest of the World. Therefore, the SAM can be written as,

$$X = AX + Y_{exo} \quad (1)$$

$$\text{Or } X = (I - A)^{-1}Y_{exo} \quad (2)$$

If we denote $(I-A)^{-1}$ matrix as M , then equation (2) can be written as

$$X = MY_{exo}, \quad (3)$$

where M is the SAM multiplier matrix, with a representative element m_{ij} as total (direct + indirect + induced) impact on account i due to change in exogenous injections in account j .

To analyse the effect of change in exogenous sector on labour demand, we need to estimate employment multiplier. For that, first, we need to estimate employment coefficient e_j of sector j , which is the ratio of number of jobs E_j to the output X_j (Equation 4). Total effect on employment as a result of change in exogenous account is estimated by Equation 5. Employment multiplier, which captures the effect of change in exogenous sector on labour demand, is estimated as $M(I-A)^{-1}$.

$$e_j = \frac{E_j}{X_j} \quad (4)$$

$$T = M(I - A)^{-1}Y \quad (5)$$

SAM multiplier has several applications. For instance, to capture the impact on production activities due to increased spending by the household, one needs to consider the column of the household sector corresponding to the rows of the activity sectors of M matrix (i.e. $M_{\text{activity by households}}$). Similarly, to understand the impact of increased production activities on household, we need to look at the column of activity sectors corresponding to the rows of the household sector of matrix M , (i.e. $M_{\text{households by activity}}$). Each variation unit in the exogenous account (Y_{exo}) affects the endogenous account (X) by M . The accounting multiplier matrix in the SAM framework captures the overall impacts of the variations in a particular sector, along with other sectors within the economy.

3. Results and Discussion

The focus of the paper is to generate a SAM for India for the year 2021-22. The SAM we generated is a 59×59 matrix, where there are 30 production sectors; 3 factors of production, viz. skilled labour, unskilled labour, capital; direct and commodity tax; 10 categories of households (rural and urban- each with 5 decile groups); government; public non-departmental enterprises; and private corporations. At the first step, a 39-

sector input-output table for India for the year 2021-22 is prepared, and then it is extended to SAM, following the methodology described above. Both the tables are shared as Appendix Table II and III in Supplementary Material, because of space constraint. The SAM helps us to analyse the structure of the economy, employment implication and the consequences of India's energy policy targets on employment generation.

3.1. Structure of the Indian Economy: Some Observations from SAM

The structure of Indian economy can be outlined from the SAM. Table 5 shows that the service sector is fuelling the growth in Indian Economy in 2021-22. In broad classification, the service sector, including transport has highest contribution to the GDP with 51% share while manufacturing sector's contribution (including construction) is at 26%, agriculture at 20% and energy at 4%.

Table 5: Sectoral Share of GDP in total GDP of the year 2021-22 (Unit: Rs Crore)

	GDP at basic prices (Rs. Crore)	Sector wise share
Agriculture & allied	4106298	18.0%
Primary Energy	272561	1.2%
Mining	218757	1.0%
Commercial energy from fossil fuel	495426	2.2%
Commercial energy from non-fossil fuel	159687	0.7%
Manufacturing	3935392	17.2%
Construction	1928710	8.5%
Transport	1089319	4.8%
Other services	10618273	46.5%
Total	22824423	100.0%

Source: Authors' estimate.

Figure 5 shows that labour intensity is still quite high in agriculture and allied sector, because still agriculture provides subsistence job to Indian population. But largely, the labour intake happens for unskilled workers. Skilled labour intensity is high for services sector and non-fossil fuel-based commercial energy.

Indian economic structure with service sector bias positions the economy in an advantageous position in the current climate change debate. Because of relatively low energy intensity of service sector from production side or supply side, Indian economy enjoys the benefit of relatively low energy intensity. Over all, the energy intensity of Indian economy is 0.073. Here, we want to mention that capital estimates include land, so is capital intensity estimates.

Figure 5 Labour, Capital and Energy Intensity

Source: Authors' estimates.

Our SAM indicates that the households belonging to lowest income quintile in rural areas spend major part (i.e. 33%) of their consumption expenditure on agriculture commodities as compared to other commodities, while the lowest quintile group in urban areas spends only 28% of their consumption expenditure on agriculture commodities. The lowest quintile in rural areas is spending 40% of their consumption expenditure on manufacturing goods, which might be caused by the advent of mobile and other consumption goods which are now perceived as a necessary commodity. On the contrary, the highest income quintile in urban areas spends only 9% of their consumption expenditure on agriculture commodities while spends 65% of their consumption expenditure on services. Both for rural and urban areas, as income grows, people tend to spend less on agriculture commodities and more on services.

3.2. Employment Implications Towards Energy Sector

In this study we have estimated SAM multiplier for some broad sectors, namely agriculture, energy, manufacturing, transport and other services. The results are shown in Table 6. Output multiplier shows how much a sector's output would increase if there is an exogenous shock of unit in the economy. The addition of the columns of the multiplier matrix shows the output multiplier, which reveals the total effect of an exogenous shock received by an endogenous account on the rest of economic activity (Cardenete & Garcia-Tapial 2019). Results show that for one unit change in exogenous sector, output in agriculture and allied activities increase by 6.656 units. Similarly, the effect of increase in 1 unit exogenous account would increase the output of Commercial energy from fossil fuel by 4.132 units, while similar change in exogenous account would increase output of Commercial energy from non-fossil fuel by 6.327 units. For labour demand, 1 unit of increase in exogenous account would increase the labour demand in

Commercial energy from fossil fuel by 2.9 units, while similar change in exogenous account would increase labour demand in commercial energy from non-fossil fuel by 7.0 units. So, our results show that multiplier effect on electricity generation from non-fossil fuel energy sources has larger effect on output and labour demand as compared to electricity generation from fossil fuel energy sources. Agriculture has the highest output multiplier followed by services, construction, transport, Commercial energy from non-fossil fuel and manufacturing. The labour demand multiplier is highest in the case of agriculture. The other sectors contributing to high returns to labour are construction, services and transport.

Table 6: SAM Multiplier for Broad Sector

	Output Multiplier	Labour Demand Multiplier
Agriculture & allied	6.656	271.0
Primary Energy	2.355	0.6
Mining	5.253	11.4
Commercial energy from fossil fuel	4.132	2.9
Commercial energy from non-fossil fuel	6.327	7.0
Manufacturing	5.367	18.5
Construction	6.453	75.3
Transport	6.332	47.1
Other services	6.440	47.9

Source: Authors' estimates.

3.3. Implication of India's Environmental Policy Target

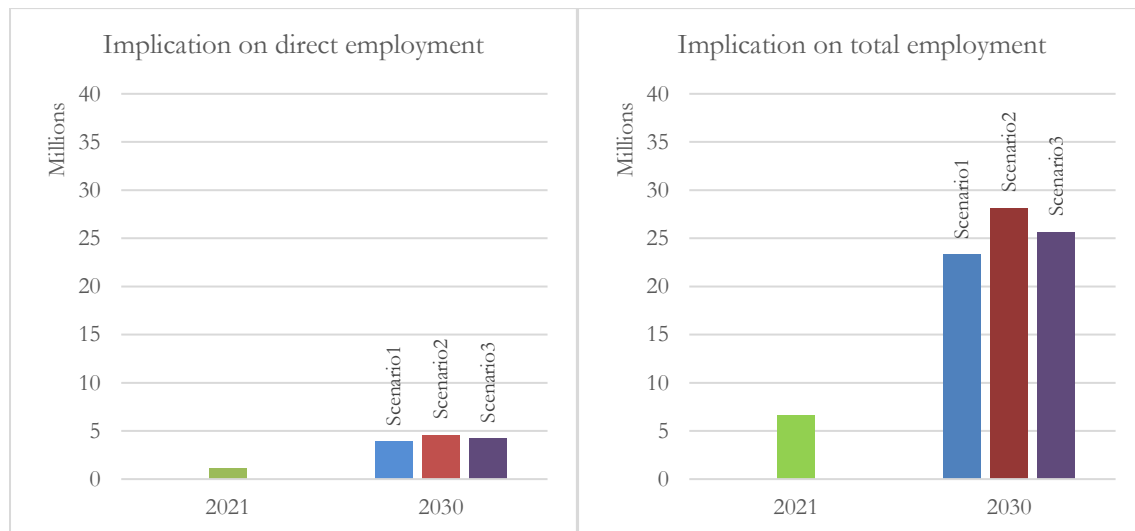

As an application of the newly constructed SAM, we have analysed the employment implication of India's Nationally Determined Contribution (NDC) emission commitments. India first submitted its Intended Nationally Determined Contribution (NDC) to UNFCCC in 2015, with two quantitative targets which are: to make cumulative electric power installed capacity from non-fossil sources 40% by 2030, to reduce the emission intensity of GDP by 33 to 35 percent compared to 2005 levels and making the carbon sink of 2.5 to 3 billion tonnes of CO2 equivalent with forest and tree cover. In the updated Nationally Determined Contribution (NDC) to be communicated to the United Nations Framework Convention on Climate Change (UNFCCC) in 2022, India sets its target to reduce Emissions Intensity of its GDP by 45 percent by 2030, from 2005 level and to reach about 50 percent cumulative electric power installed capacity from non-fossil fuel-based energy resources by 2030. Achieving this target requires a shift in technology, which would have implication on the overall economy. Presently the share of renewables in power generation in India is only 12% (as of February 2023). Coal is still the dominant source of energy for power generation (73% in 2023) in India. With increased focus on promotion of renewable energy and policy initiatives to achieve the net zero target, the energy sector is going through a transition phase, and there would be impact of the transition on the socio-economic factors like employment. In this section, we want to explore the impact of the targets on electricity generation from

renewable energy sources on Indian economy, as an application of our SAM along with the Periodic Labour Force Survey data on labour force participation and data on energy sector from India Climate & Energy Dashboard published by NITI Aayog.

We have developed three scenarios for the analysis. (1) Scenario 1 assumes the present composition of energy generation in 2030. (2) Scenario 2 assumes that renewable’s share in electricity generation is increased to 50% in 2030. (3) India targets to ramp up the share of installed capacity of electricity generation from renewables to 50% of total installed capacity by 2030, but installation does not always translate into generation, so in Scenario 3, we assumed that renewable’s share in electricity generation would become 30% in 2030. All the scenarios are based on 6% growth rate of energy demand, which is the average growth rate of energy generation between 2018-19 to 2022-23.

Our estimates show that the present composition of energy generation (Scenario 1) would provide direct employment to 3.9 million people in 2030, vis-à-vis employment of 1.1 million people in energy sector in 2021 (Figure 6). If renewable’s share in electricity generation is increased to 50% (Scenario 2), it would provide direct employment to 4.5 million people in 2030. Under Scenario 3, direct employment is provided to 4.5 million people in 2030 in energy sector.

Figure 6: Implication of India’s Renewable Energy Policy Emphasis on Employment

Source: Authors’ estimates.

Energy sector is linked with other sectors of the economy through forward and backward linkage, which is captured by the Social Accounting Matrix in our study. So, the impact of employment generation through the environmental policy interventions is not limited to the energy sector only. It generates employment in the sectors which provide input to the electricity generation sector and also generates employment in all sectors through the income effect that it generates in the process. Capturing these two effects, other than direct employment generation, we can see that energy sector, in total, provides employment to 6.6 million people in India in 2021. With present composition

of electricity generation, under Scenario 1, energy sector would provide employment to a total of 23.3 million people, directly or indirectly, in 2030. Under both Scenario 1 and Scenario 2, employment generation is higher as compared to Scenario 1 in 2030. Under Scenario 2, 28.1 million of total employment, and under Scenario 3, 25.7 million of total employment are provided through the interlinkage of other sectors with energy sector. This shows that India's emphasis towards renewable energy sector would not only be beneficial for employment generation in energy sector, but also it generates employment in other sectors too.

4. Concluding Remarks

SAM as a policy tool has wide applications for macro-economic analysis, and thus, the matrix is generated and utilised for designing policies in many countries. SAMs of Indian economy generated so far are mostly based on Input-Output table in the past and none have tried to disaggregate the energy sector to apprehend renewable energy sectors. In view of the importance of the analysis of renewable and non-renewable energy sectors in a growing developing economy like India, such disaggregation is very important for policy design and implementation. Also, Government of India currently publishes Supply-Use table instead of Input-Output table. This paper provides a detailed narrative of the methodology of construction of Input-Output table, and, subsequently construction of a SAM, which is not lucidly covered in literature. Both the tables, which capture structural aspects of the economy, can be utilised for several environmental policy related research. Capturing the methodological nuances using a large set of databases for India and highlighting the usefulness of such framework in energy and environmental policy analysis have been the two motivating factors for the research.

The SAM highlights the income distribution across the occupational classes, which has an important role as an information system. The SAM not only talks about the structure of the economy, it indicates the spending pattern of the households across rural and urban income decile groups.

SAM multiplier provides a useful tool to understand the different linkages in the economy. Our analysis indicates that the labour demand multiplier is higher for agriculture and services sector, but the magnitudes differ because agriculture still absorbs majority of the unskilled labour force. Nonetheless, these two sectors will play a key role in employment generation for the Indian economy. This is particular of importance since inclusive growth is the focus of the policy-makers at present.

To illustrate the use of SAM, we have also assessed the impact of India's environmental policy initiatives in the context of employment generation. Our results show that India's policy emphasis on greater reliance on renewable energy sources for power generation would not only generate jobs in the electricity generation sector, but also would increase overall employment as compared to the present composition of electricity generation sources.

Although SAM has significantly extended the multi-sectoral framework of the IO table, it still falls short in representing elements such as pollutants, environmental quality, natural resources, and their interactions with economic activities. In future, we want to work along this line.

Appendix I.ii: Description of 140 Products in Supply-Use table 2018-19

S. No.	Products	S. No.	Products	S. No.	Products
1	Paddy	48	Sugar	95	Electrical industrial machinery
2	Wheat	49	Bread & Bakery products	96	Electrical cables, wires
3	Coarse cereals	50	Miscellaneous food products	97	Batteries
4	Gram	51	Alcoholic beverages	98	Electrical appliances
5	Arhar	52	Non-alcoholic beverages	99	Communication equipment
6	Other pulses	53	Tea processed	100	Other electrical machinery
7	Groundnut	54	Coffee processed	101	Electronic equipment including T.V.
8	Rapeseed and mustard	55	Tobacco Products	102	Medical precision, optical instrument
9	Other oil seeds	56	Cotton Yarn and Cotton Textiles	103	Watches and clocks
10	kapas	57	Synthetic yarn and synthetic textiles	104	Ships and boats
11	jute, hemp and mesta	58	Wool yarn and woolen textiles	105	Rail equipment
12	Sugarcane	59	Silk yarn and silk textiles	106	Motor vehicles
13	Coconut	60	Carpet weaving	107	Motor cycles and scooters
14	Tobacco	61	Readymade garments	108	Bicycles, cycle-rickshaw
15	Tea	62	Misc. textile products	109	Aircrafts & Spacecrafts
16	Coffee	63	Leather footwear	110	Other transport equipment
17	Rubber	64	Leather and leather products except footwear	111	Gems & jewellery
18	Fruits	65	Wood and wood products except furniture	112	Miscellaneous manufacturing
19	Vegetables	66	Paper, Paper products and newsprint	113	Construction and construction services
20	Other food crops	67	Publishing, printing and allied activities	114	Electricity
21	Milk	68	Furniture & Fixtures	115	Gas
22	Wool	69	Rubber products	116	Water Supply
23	Egg and poultry	70	Plastic products	117	Trade
24	Other livestock products	71	Petroleum products	118	Repair & Maintenance of Motor Vehicle
25	Industry Wood	72	Coal tar products	119	Hotels & Restaurant
26	Firewood	73	Inorganic chemicals	120	Railway Transport
27	Other forestry products	74	Organic chemicals	121	Land transport

28	Inland Fish	75	Fertilizers	122	Air transport
29	Marine Fish	76	Pesticides	123	Water Transport
30	Coal and Lignite	77	Paints, varnishes and lacquers	124	Supportive and Auxiliary transport activities
31	Natural Gas	78	Drugs and medicine	125	Storage and warehousing
32	Crude petroleum	79	Soaps, cosmetics and glycerine	126	Communication services
33	Iron ore	80	Synthetic fibres, resin	127	Financial services
34	Manganese ore	81	Other chemicals and chemical products	128	Insurance services
35	Bauxite	82	Cement	129	Ownership of dwellings
36	Copper ore	83	Non-metallic mineral products	130	Real estate services
37	Other Metallic minerals	84	Iron and steel Ferro alloys	131	Renting of machinery & equipment
38	Limestone	85	Iron and steel casting and forging	132	Research & Development Services
39	Mica	86	Iron and steel foundries	133	Legal services
40	Other non-metallic minerals	87	Non-ferrous basic metals (including alloys)	134	Other Business services
41	Processed poultry meat & poultry meat products	88	Hand tools, hardware	135	Computer related services
42	Processed other meat & meat products	89	Miscellaneous metal products	136	Public administration and defence
43	Processed fish & fish products	90	Tractors and other agricultural implements	137	Education services
44	Processed fruits & Processed Vegetables	91	Industrial machinery for food and textile industry	138	Human health and social care services
45	Dairy products	92	Industrial machinery (except food and textile)	139	Community, social and personal services
46	Edible Oils and Fats	93	Machine tools	140	Recreation, entertainment and radio & TV broadcasting and other services
47	Grain Mill products, starch and starch products	94	Other non-electrical machinery		

Appendix I.ii: Description of 66 Products in Supply-Use table 2018-19

S. No.	Sector	S. No.	Sector	S. No.	Sector
1	Agriculture	23	Manufacture of electronic component, consumer electronics, magnetic and optical media	45	Railway Transport
2	Livestock	24	Manufacture of computer and peripheral equipment	46	Land Transport
3	Forestry and Logging	25	Manufacture of communication equipments	47	Water Transport
4	Fishing & Aquaculture	26	Manufacture of optical and electronics products n.e.c.	48	Air Transport
5	Coal & Lignite	27	Manufacture of Electrical equipments	49	Supportive & Auxiliary transport activities
6	Crude Petroleum	28	Manufacture of machinery and equipments n.e.c.	50	Storage & warehousing
7	Natural Gas	29	Manufacture of Transport	51	Communication
8	Iron Ore	30	Manufacture of coke and refined petroleum products	52	Trade
9	Non-ferrous metal ores	31	Manufacture of chemical and chemical products except pharmaceuticals, medicinal and botanical products	53	Hotels & Restaurant
10	Other Mining	32	Manufacture of pharmaceutical; medicinal chemicals and botanical products	54	Financial Services
11	Production, processing and preservation of meat, fish, fruit, vegetables, oils and fats	33	Manufacture of rubber & plastic products	55	Insurance Services
12	Manufacture of dairy products	34	Manufacture of other non-metallic mineral products	56	Ownership of dwellings
13	Manufacture of grain mill products, etc. and animal feeds	35	Manufacture of wood and of products of wood and cork, except furniture; manufacture of articles of straw and plaiting material	57	Education & Research
14	Manufacture of other food products	36	Manufacture of paper and paper products	58	Medical and Health
15	Manufacture of beverages	37	Printing and reproduction of recorded media except publishing	59	Legal Services

16	Manufacture of tobacco products	38	Manufacture of furniture	60	Computer related services
17	Manufacture of textiles + cotton ginning	39	Other Manufacturing	61	Other Business services
18	Manufacture of wearing apparel, except custom tailoring	40	Repair and installation of machinery and equipments	62	Real estate activities
19	Manufacture of leather and related products	41	Construction	63	Renting of machinery and equipment
20	Manufacture of Basic Iron and Steel + Casting of iron and steel	42	Electricity	64	Community, Social & personal services
21	Manufacture of basic precious and non-ferrous metals + Casting of non-ferrous metals	43	Gas	65	Other services
22	Manufacture of fabricated metal products, except machinery and equipments	44	Water supply	66	Public administration. & defence
